

## 15-859(B) Machine Learning Learning finite state environments

Avrim Blum  
03/26/08

### Consider the following setting

- Say we are a baby trying to figure out the effects our actions have on our environment...
  - Perform actions
  - Get observations
  - Try to make an internal model of what is happening.

### A model: learning a finite state environment

- Let's model the world as a DFA. We perform actions, we get observations.
- Our actions can also change the state of the world. # states is finite.

### Another way to put it

- We have a box with buttons and lights.

- Can press the buttons, observe the lights.
  - $lights = f(current\ state)$
  - $next\ state = g(button, current\ state)$
- **Goal: learn predictive model of device.**

### Learning a DFA

In the language of our standard models...

- Asking if we can learn a DFA from Membership Queries.
  - Issue of whether we have counterexamples (Equivalence Queries) or not. [for the moment, assume not]
  - Also issue of whether or not we have a reset button. [for today, assume yes]

### Learning DFAs

This seems really hard. Can't tell for sure when world state has changed.

Let's look at an easier problem first: state = observation.

## An example w/o hidden state

2 actions: a, b.

Generic algorithm for lights=state:

- Build a model.
- While not done, find an unexplored edge and take it.

Now, let's try the harder problem!

## Some examples

Example #1 (3 states)

Example #2 (3 states)

## Can we design a procedure to do this in general?

One problem: what if we always see the same thing? How do we know there isn't something else out there?

Our model:

Real world:

Called "combination-lock automaton"

## Can we design a procedure to do this in general?

Combination-lock automaton: basically simulating a conjunction.

This means we can't hope to efficiently come up with an exact model of the world from just our own experimentation. (I.e., MQs only).

## How to get around this?

- Assume we can propose model and get counterexample. (MQ+EQ)
- Equivalently, goal is to be predictive. Any time we make a mistake, we think and perform experiments. (MQ+MB)
- Goal is not to have to do this too many times. For our algorithm, total # mistakes will be at most # states.

## Algorithm by Dana Angluin

(with extensions by Rivest & Schapire)

- To simplify things, let's assume we have a RESET button. [Back to basic DFA problem]
- Can get rid of that using something called a "homing sequence" that you can also learn.

## The problem (recap)

- We have a DFA:

- $observation = f(current\ state)$
- $next\ state = g(button, prev\ state)$
- Can feed in sequence of actions, get observations. Then resets to start.
- Can also propose/field-test model. Get counterexample.

## Key Idea

Key idea is to represent the DFA using a state/experiment table.

		experiments	
		$\lambda$	a
states	$\lambda$	<input type="checkbox"/>	<input type="checkbox"/>
	a	<input type="checkbox"/>	<input type="checkbox"/>
	b	<input type="checkbox"/>	<input type="checkbox"/>
transitions	aa	<input type="checkbox"/>	<input type="checkbox"/>
	ab	<input type="checkbox"/>	<input type="checkbox"/>
	ba	<input type="checkbox"/>	<input type="checkbox"/>
	bb	<input type="checkbox"/>	<input type="checkbox"/>

## Key Idea

Key idea is to represent the DFA using a state/experiment table.

		experiments	
		$\lambda$	a
states	$\lambda$	<input type="checkbox"/>	<input type="checkbox"/>
	a	<input type="checkbox"/>	<input type="checkbox"/>
	b	<input type="checkbox"/>	<input type="checkbox"/>
transitions	aa	<input type="checkbox"/>	<input type="checkbox"/>
	ab	<input type="checkbox"/>	<input type="checkbox"/>
	ba	<input type="checkbox"/>	<input type="checkbox"/>
	bb	<input type="checkbox"/>	<input type="checkbox"/>

Guarantee will be: either this is correct, or else the world has  $> n$  states. In that case, need way of using counterexs to add new state to model.

## The algorithm

We'll do it by example...

## Algorithm (formally)

Begin with  $S = \{\lambda\}, E = \{\lambda\}$ .

1. Fill in transitions to make a hypothesis FSM.
2. While exists  $s \in SA$  such that no  $s' \in S$  has  $row(s') = row(s)$ , add  $s$  into  $S$ , and go to 1.
3. Query for counterexample  $z$ .
4. Consider all splits of  $z$  into  $(p_i, s_i)$ , and replace  $p_i$  with its predicted equivalent  $\alpha_i \in S$ .
5. Find  $\alpha_i r_i$  and  $\alpha_{i+1} r_{i+1}$  that produce different observations.
6. Add  $r_{i+1}$  as a new experiment into  $E$ . go to 1.
