Estimating Parameters

• Maximum Likelihood Estimate (MLE): choose θ that maximizes probability of observed data $\mathcal D$

$$\hat{\theta} = \arg \max_{\theta} P(\mathcal{D} \mid \theta)$$

• Maximum a Posteriori (MAP) estimate: choose θ that is most probable given prior probability and the data

$$\begin{split} \widehat{\theta} &= \arg\max_{\theta} \ P(\theta \mid \mathcal{D}) \\ &= \arg\max_{\theta} \ = \ \frac{P(\mathcal{D} \mid \theta)P(\theta)}{P(\mathcal{D})} \end{split}$$

Conjugate priors

- $P(\theta)$ and $P(\theta \mid D)$ have the same form
- Eg. 1 Coin flip problem

Likelihood is ~ Binomial

$$P(\mathcal{D} \mid \theta) = \theta^{\alpha_H} (1 - \theta)^{\alpha_T}$$

If prior is Beta distribution,

$$P(\theta) = \frac{\theta^{\beta_H - 1} (1 - \theta)^{\beta_T - 1}}{B(\beta_H, \beta_T)} \sim Beta(\beta_H, \beta_T)$$

Then posterior is Beta distribution

$$P(\theta|D) \sim Beta(\beta_H + \alpha_H, \beta_T + \alpha_T)$$

For Binomial, conjugate prior is Beta distribution.

[A. Singh]

Conjugate priors

- $P(\theta)$ and $P(\theta \mid D)$ have the same form
- Eg. 2 Dice roll problem (6 outcomes instead of 2)

Likelihood is ~ Multinomial(
$$\theta = \{\theta_1, \theta_2, \dots, \theta_k\}$$
)

$$P(\mathcal{D} \mid \theta) = \theta_1^{\alpha_1} \theta_2^{\alpha_2} \dots \theta_k^{\alpha_k}$$

If prior is Dirichlet distribution,

$$P(\theta) = \frac{\theta_1^{\beta_1 - 1} \theta_2^{\beta_2 - 1} \dots \theta_k^{\beta_k - 1}}{B(\beta_1, \beta_2, \dots \beta_K)} \sim \text{Dirichlet}(\beta_1 \dots \beta_k)$$

Then posterior is Dirichlet distribution

$$P(\theta|D) \sim \text{Dirichlet}(\beta_1 + \alpha_1, \dots, \beta_k + \alpha_k)$$

For Multinomial, conjugate prior is Dirichlet distribution.

[A. Singh]

Conjugate priors

- $P(\theta)$ and $P(\theta \mid D)$ have the same form
- Eg. 2 Dice roll problem (6 outcomes instead of 2

Likelihood is \sim Multinomial($\theta = \{\theta_1, \theta_2, ..., \theta_n\}$

$$P(\mathcal{D} \mid \theta) = \theta_1^{\alpha_1} \theta_2^{\alpha_2} \dots \theta_k^{\alpha_k}$$

If prior is Dirichlet distribution,

$$P(\theta) = \frac{\theta_1^{\beta_1 - 1} \theta_2^{\beta_2 - 1} \dots \theta_k^{\beta_k - 1}}{B(\beta_1, \beta_2, \dots \beta_K)} \sim \text{Dirichlet}$$

Then posterior is Dirichlet distribution

$$P(\theta|D) \sim \text{Dirichlet}(\beta_1 + \alpha_1, \dots, \beta_k + \alpha_k)$$

For Multinomial, conjugate prior is Dirichlet distribution.

[A. Singh]

Let's learn classifiers by learning P(Y|X)

Consider Y=Wealth, X=<Gender, HoursWorked>

Gender	HrsWorked	P(rich G,HW)	P(poor G,HW)
F	<40.5	.09	.91
F	>40.5	.21	.79
М	<40.5	.23	.77
М	>40.5	.38	.62

How many parameters must we estimate?

Suppose $X = \langle X_1, ..., X_n \rangle$ where X_i and Y are boolean RV's

Gender	HrsWorked	P(rich G,HW)	P(poor G,HW)
F	<40.5	.09	.91
F	>40.5	.21	.79
М	<40.5	.23	.77
М	>40.5	.38	.62

To estimate $P(Y|X_1, X_2, ... X_n)$

If we have 30 boolean X_i 's: $P(Y | X_1, X_2, ... X_{30})$

Bayes Rule

$$P(Y|X) = \frac{P(X|Y)P(Y)}{P(X)}$$

Which is shorthand for:

$$(\forall i, j) P(Y = y_i | X = x_j) = \frac{P(X = x_j | Y = y_i) P(Y = y_i)}{P(X = x_j)}$$

Equivalently:

$$(\forall i, j) P(Y = y_i | X = x_j) = \frac{P(X = x_j | Y = y_i) P(Y = y_i)}{\sum_k P(X = x_j | Y = y_k) P(Y = y_k)}$$

Can we reduce params using Bayes Rule?

Suppose X =1,... X_n> where X_i and Y are boolean RV's
$$P(Y|X) = \frac{P(X|Y)P(Y)}{P(X)}$$

Naïve Bayes

Naïve Bayes assumes

$$P(X_1 ... X_n | Y) = \prod_i P(X_i | Y)$$

i.e., that X_i and X_j are conditionally independent given Y, for all i≠j

Conditional Independence

Definition: X is <u>conditionally independent</u> of Y given Z, if the probability distribution governing X is independent of the value of Y, given the value of Z

$$(\forall i, j, k) P(X = x_i | Y = y_j, Z = z_k) = P(X = x_i | Z = z_k)$$

Which we often write

$$P(X|Y,Z) = P(X|Z)$$

E.g.,

P(Thunder|Rain, Lightning) = P(Thunder|Lightning)

Naïve Bayes uses assumption that the X_i are conditionally independent, given Y

Given this assumption, then:

$$P(X_1, X_2|Y) = P(X_1|X_2, Y)P(X_2|Y)$$

= $P(X_1|Y)P(X_2|Y)$

in general:
$$P(X_1...X_n|Y) = \prod_i P(X_i|Y)$$

How many parameters to describe $P(X_1...X_n|Y)$? P(Y)?

- · Without conditional indep assumption?
- · With conditional indep assumption?

Naïve Bayes in a Nutshell

Bayes rule:

$$P(Y = y_k | X_1 ... X_n) = \frac{P(Y = y_k) P(X_1 ... X_n | Y = y_k)}{\sum_j P(Y = y_j) P(X_1 ... X_n | Y = y_j)}$$

Assuming conditional independence among X_i's:
$$P(Y = y_k | X_1 \dots X_n) = \frac{P(Y = y_k) \prod_i P(X_i | Y = y_k)}{\sum_j P(Y = y_j) \prod_i P(X_i | Y = y_j)}$$

So, to pick most probable Y for $X^{new} = \langle X_1, ..., X_n \rangle$

$$Y^{new} \leftarrow \arg\max_{y_k} \ P(Y = y_k) \prod_i P(X_i^{new} | Y = y_k)$$

Naïve Bayes Algorithm – discrete X_i

- Train Naïve Bayes (examples) for each* value y_k estimate $\pi_k \equiv P(Y = y_k)$ for each* value x_{ij} of each attribute X_i estimate $\theta_{ijk} \equiv P(X_i = x_{ij}|Y = y_k)$
- Classify (X^{new})
 $$\begin{split} Y^{new} &\leftarrow \arg\max_{y_k} \ P(Y = y_k) \prod_i P(X_i^{new} | Y = y_k) \\ Y^{new} &\leftarrow \arg\max_{y_k} \ \pi_k \prod_i \theta_{ijk} \end{split}$$

probabilities must sum to 1, so need estimate only n-1 of these...

Estimating Parameters: Y, X_i discrete-valued

Maximum likelihood estimates (MLE's):

$$\hat{\pi}_k = \hat{P}(Y = y_k) = \frac{\#D\{Y = y_k\}}{|D|}$$

$$\hat{\theta}_{ijk} = \hat{P}(X_i = x_{ij}|Y = y_k) = \frac{\#D\{X_i = x_{ij} \land Y = y_k\}}{\#D\{Y = y_k\}}$$

Number of items in dataset D for which $Y=y_k$

Example: Live in Sq Hill? P(S|G,D,E)

- S=1 iff live in Squirrel Hill
- D=1 iff Drive to CMU
- G=1 iff shop at SH Giant Eagle
 - E=1 iff even # of letters in last name

What probability parameters must we estimate?

Example: Live in Sq Hill? P(S|G,D,E)

- S=1 iff live in Squirrel Hill
- D=1 iff Drive or Carpool to CMU
- G=1 iff shop at SH Giant Eagle
- E=1 iff Even # letters last name

```
\begin{array}{lll} P(S=1): & P(S=0): \\ P(D=1 \mid S=1): & P(D=0 \mid S=1): \\ P(D=1 \mid S=0): & P(D=0 \mid S=0): \\ P(G=1 \mid S=1): & P(G=0 \mid S=1): \\ P(G=1 \mid S=0): & P(G=0 \mid S=0): \\ P(E=1 \mid S=1): & P(E=0 \mid S=1): \\ P(E=0 \mid S=0): & P(E=0 \mid S=0): \\ \end{array}
```

Naïve Bayes: Subtlety #1

If unlucky, our MLE estimate for $P(X_i | Y)$ might be zero. (e.g., X_i = Birthday_Is_January_30_1990)

- Why worry about just one parameter out of many?
- · What can be done to avoid this?

Estimating Parameters

Maximum Likelihood Estimate (MLE): choose θ that maximizes probability of observed data \mathcal{D}

$$\hat{\theta} = \arg \max_{\theta} P(\mathcal{D} \mid \theta)$$

 Maximum a Posteriori (MAP) estimate: choose θ that is most probable given prior probability and the data

$$\widehat{\theta} = \arg \max_{\theta} \ P(\theta \mid \mathcal{D})$$

$$= \arg \max_{\theta} \ = \frac{P(\mathcal{D} \mid \theta)P(\theta)}{P(\mathcal{D})}$$

Estimating Parameters: *Y*, *X*_i discrete-valued

Maximum likelihood estimates:

$$\hat{\pi}_k = \hat{P}(Y = y_k) = \frac{\#D\{Y = y_k\}}{|D|}$$

$$\hat{\theta}_{ijk} = \hat{P}(X_i = x_j | Y = y_k) = \frac{\#D\{X_i = x_j \land Y = y_k\}}{\#D\{Y = y_k\}}$$

MAP estimates (Beta, Dirichlet priors):

$$\hat{\pi}_k = \hat{P}(Y = y_k) = \frac{\#D\{Y = y_k\} + (\beta_k - 1)}{|D| + \sum_m (\beta_m - 1)}$$
 "imaginary" examples
$$\hat{\theta}_{ijk} = \hat{P}(X_i = x_j | Y = y_k) = \frac{\#D\{X_i = x_j \land Y = y_k\} + (\beta_k - 1)}{\#D\{Y = y_k\} + \sum_m (\beta_m - 1)}$$

Only difference:

Naïve Bayes: Subtlety #2

Often the X_i are not really conditionally independent

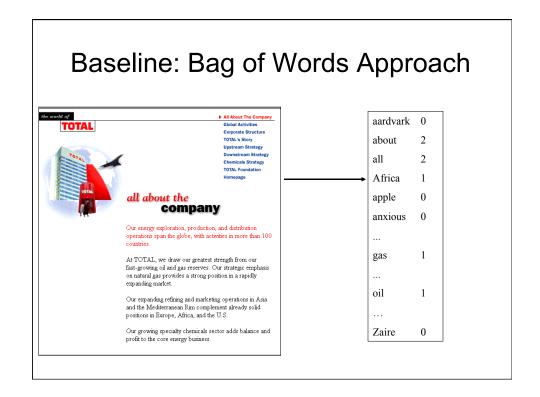

- We use Naïve Bayes in many cases anyway, and it often works pretty well
 - often the right classification, even when not the right probability (see [Domingos&Pazzani, 1996])
- What is effect on estimated P(Y|X)?
 - Special case: what if we add two copies: $X_i = X_k$

Special case: what if we add two copies: $X_i = X_k$

Learning to classify text documents

- · Classify which emails are spam?
- · Classify which emails promise an attachment?
- · Classify which web pages are student home pages?

How shall we represent text documents for Naïve Bayes?

Learning to classify document: P(Y|X) the "Bag of Words" model

- · Y discrete valued. e.g., Spam or not
- $X = \langle X_1, X_2, ... X_n \rangle = document$
- X_i is a random variable describing the word at position i in the document
- possible values for X_i: any word w_k in English
- Document = bag of words: the vector of counts for all w_k's
 - (like #heads, #tails, but we have more than 2 values)

Naïve Bayes Algorithm – discrete X_i

Train Naïve Bayes (examples)

for each value y_k

estimate
$$\pi_k \equiv P(Y = y_k)$$

for each value x_i of each attribute X_i

estimate
$$\theta_{ijk} \equiv P(X_i = x_j | Y = y_k)$$

prob that word x_j appears in position i, given $Y=y_k$

• Classify (*X*^{new})

$$\begin{split} Y^{new} &\leftarrow \arg\max_{y_k} \ P(Y = y_k) \prod_i P(X_i^{new} | Y = y_k) \\ Y^{new} &\leftarrow \arg\max_{y_k} \ \pi_k \prod_i \theta_{ijk} \end{split}$$

^{*} Additional assumption: word probabilities are position independent $\theta_{ijk}=\theta_{mjk}~~{
m for~all}~i,m$

MAP estimates for bag of words

Map estimate for multinomial

$$\theta_i = \frac{\alpha_i + \beta_i - 1}{\sum_{m=1}^k \alpha_m + \sum_{m=1}^k (\beta_m - 1)}$$

 $\theta_{aardvark} = P(X_i = \text{aardvark}) = \frac{\text{\# observed 'aardvark'} + \text{\# hallucinated 'aardvark'} - 1}{\text{\# observed words } + \text{\# hallucinated words} - k}$

Naive Bayes: 89% classification accuracy

What you should know:

- Training and using classifiers based on Bayes rule
- Conditional independence
 - What it is
 - Why it's important
- Naïve Bayes
 - What it is
 - Why we use it so much
 - Training using MLE, MAP estimates
 - Discrete variables and continuous (Gaussian)

Questions:

- What error will the classifier achieve if Naïve Bayes assumption is satisfied and we have infinite training data?
- Can you use Naïve Bayes for a combination of discrete and real-valued X_i?
- How can we extend Naïve Bayes if just 2 of the n X_i are dependent?
- What does the decision surface of a Naïve Bayes classifier look like?
