

UNIT 8C

Computer Organization: The Machine's Language

15110 Principles of Computing,
Carnegie Mellon University - CORTINA

1

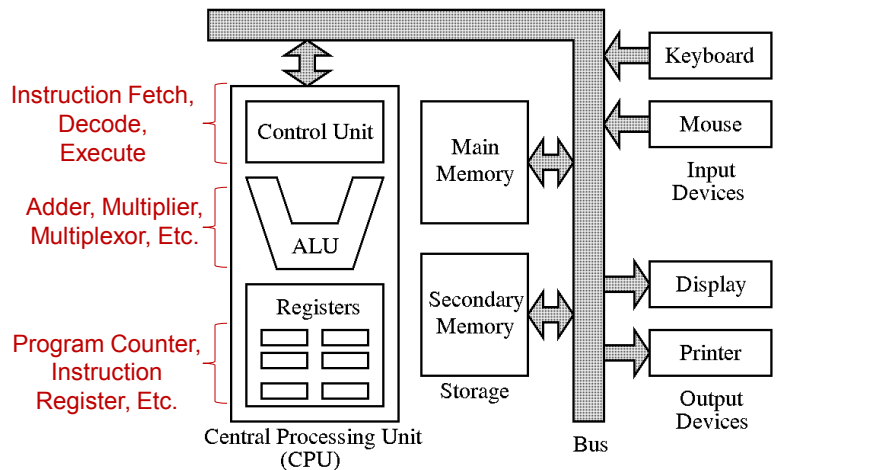

von Neumann Architecture

- Modern computers include **control logic** that implements the **fetch-decode-execute** cycle introduced by John von Neumann:
 - Fetch next instruction from memory.
 - Decode instruction and get any data it needs (possibly from memory).
 - Execute instruction with data and store results (possibly into memory).
 - Repeat.

15110 Principles of Computing,
Carnegie Mellon University - CORTINA

2

Stored Program Computer

<http://cse.iitkgp.ac.in/pds/notes/intro.html>

15110 Principles of Computing,
Carnegie Mellon University - CORTINA

3

MARS

Memory Array Redcode Simulator

- A simulated computer system that we can use to explore how to run instructions at the machine level.
 - To use this in Ruby, we need to do:
include MARSLab
- We can program this virtual machine in assembly language (a human readable form of machine language) called Redcode.

15110 Principles of Computing,
Carnegie Mellon University - CORTINA

4

MARS Instruction Format

- Memory is an array of words. (How many bits per word? Don't worry about it.)
- Each word is divided into several fields:

- OpCodes: ADD, SUB, MOV, JMP, DAT, etc.

15110 Principles of Computing,
Carnegie Mellon University - CORTINA

5

MARS Address Modes

1. **Direct** mode: the operand is at the specified address relative to the current instruction.
2. **Immediate** mode (marked by #): the operand is given in the instruction itself.
3. Other modes are provided (e.g., indirect addressing, auto-increment) but we won't cover them here. Google "RedCode" if you want to know more.

15110 Principles of Computing,
Carnegie Mellon University - CORTINA

6

Addressing Example

MOV #500, 10

- Opcode is MOV (“move data”).
- Move the value 500 to the memory location that is 10 beyond the current instruction.
- Addressing modes used:
 - A = immediate (#), operand is 500
 - B = direct, operand is 10

Addressing Example

MOV #500, 10

ADD #30, 9

- Move the value 500 to the memory location that is 10 beyond the current instruction.
- Then add the value 30 to that same location.

Memory Map

250:	MOV #500, 10
251:	ADD #30, 9
252:	DAT #0, #0
260:	DAT #0, #0

15110 Principles of Computing,
Carnegie Mellon University - CORTINA

9

Memory Map

250:	MOV #500, 10	 Program Counter
251:	ADD #30, 9	
252:	DAT #0, #0	
260:	DAT #0, #0

Carnegie Mellon University - CORTINA

10

Memory Map

250:	MOV	#500, 10	 Program Counter
251:	ADD	#30, 9	
252:	DAT	#0, #0	
260:	DAT	#0, #500	

Memory Map

250:	MOV	#500, 10	 Program Counter
251:	ADD	#30, 9	
252:	DAT	#0, #0	
260:	DAT	#0, #530	Encountering a DAT instruction halts execution.

Stupid MARS Tricks

```
600:  MOV #123, 10
601:  DAT #0
602:  JMP -2
603:  JMP -1
604:  JMP -1
605:  JMP 1
606:  JMP 0 ← Program Counter
607:  JMP 2
608:  JMP 1
609:  MOV #-42, 1
610:  DAT #97
```

15110 Principles of Computing,
Carnegie Mellon University - CORTINA

13

Stupid MARS Tricks

```
600:  MOV #123, 10
601:  DAT #0
602:  JMP -2
603:  JMP -1
604:  JMP -1
605:  JMP 1 ← Program Counter
606:  JMP 0
607:  JMP 2
608:  JMP 1
609:  MOV #-42, 1
610:  DAT #97
```

15110 Principles of Computing,
Carnegie Mellon University - CORTINA

14

Stupid MARS Tricks

```
600:  MOV #123, 10
601:  DAT #0
602:  JMP -2
603:  JMP -1
604:  JMP -1
605:  JMP 1
606:  JMP 0
607:  JMP 2 ← Program Counter
608:  JMP 1
609:  MOV #-42, 1
610:  DAT #97
```

15110 Principles of Computing,
Carnegie Mellon University - CORTINA

15

Stupid MARS Tricks

```
600:  MOV #123, 10
601:  DAT #0
602:  JMP -2
603:  JMP -1
604:  JMP -1 ← Program Counter
605:  JMP 1
606:  JMP 0
607:  JMP 2
608:  JMP 1
609:  MOV #-42, 1
610:  DAT #97
```

15110 Principles of Computing,
Carnegie Mellon University - CORTINA

16

What Does This Do?

- JMN means “jump if non-zero”
- Syntax: **JMN** *place, value*

```
ADD #1, 2
JMN -1, 1
DAT #-2000
```

- To test this, do: `m.run(9999)`

Assembly Language

- Slightly more abstract than machine language.
- Handles some of the drudgery for us.

```
foo = 500
foo = foo + 30
```

```
myprog      MOV #500, foo
            ADD #30, foo
            DAT #0, #0
            ; other stuff ...
foo         DAT #0, #0
            end myprog
```

Simple MARS Program (simple.txt)

labels opcodes operands

```
↓      ↓      ↓
x      DAT #4
y      DAT #7
simple  ADD x, y      ; add x to y
      DAT #0          ; DAT will halt
      end simple
```

DAT specifies a data value. Data values can also be instructions (e.g. "halt")

Running the Program in irb (cont'd)

```
> include MARSLab
=> Object
> m = make_test_machine("simple.txt")
=> #<MiniMARS mem = [DAT #0 #4,...] pc = [*2]>
> m.dump
0000: DAT #0 #4
0001: DAT #0 #7
0002: ADD -2 -1
0003: DAT #0 #0
=> nil
```

Program starts
at address 2 in
"memory"

```
x      DAT #4
y      DAT #7
simple  ADD x, y
      DAT #0
```

add the data 2 words back to
the data 1 word back

"memory" addresses

Running the Program in irb (cont'd)

```
> m.step  
=> ADD -2 -1  
> m.dump
```

```
0000: DAT #0 #4
```

```
0001: DAT #0 #11 ← y has been updated
```

```
0002: ADD -2 -1
```

```
0003: DAT #0 #0
```

```
=> nil
```

```
> m.status
```

```
Run: continue PC: [ *3 ]
```

x	DAT #4
y	DAT #7
simple	ADD x, y
	DAT #0

PC = Program Counter
The PC indicates where
the next instruction is
located (e.g. address 3).

Running the Program in irb (cont'd)

```
> m.step  
=> DAT #0 #0  
> m.dump
```

```
0000: DAT #0 #4
```

```
0001: DAT #0 #11
```

```
0002: ADD -2 -1
```

```
0003: DAT #0 #0
```

```
=> nil
```

```
> m.status
```

```
Run: halt
```

x	DAT #4
y	DAT #7
simple	ADD x, y
	DAT #0

nothing has changed

The MARS simulator
executed a DAT instruction
and has halted.

Looping Example

Multiply $x * y$ without using the MUL instruction.

Algorithm: Add x to an accumulator y times.

Example: Compute $5 * 9$:

x	DAT #5	
y	DAT #9	
acc	DAT #0	
mult	ADD x, acc	; add x to acc
	SUB #1, y	; subtract 1 from y
	JMN mult, y	; jump to label mult
		; if y is not zero
	end mult	

```
begin
  acc = acc + x
  y = y - 1
end while y != 0
```

15110 Principles of Computing,
Carnegie Mellon University - CORTINA

23

Flowchart of Multiply Example

15110 Principles of Computing,
Carnegie Mellon University - CORTINA

24

Running the Program in irb

```
> include MARSLab
=> Object
> m = make_test_machine("mult.txt")
=> #<MiniMARS mem = [DAT #0 #5,...] pc = [*3]>
> m.run
=> 28 ← number of instructions executed
> m.dump(0,2) ← dump (display) the
                words from "memory"
                in this range only
0000: DAT #0 #5
0001: DAT #0 #0
0002: DAT #0 #45
=> nil
```

15110 Principles of Computing,
Carnegie Mellon University - CORTINA

25

What Does This Do?

```
puzzle      MOV #1, x
             JMP 2
loop        ADD x, x
             SUB #1, count
             SLT count, zero
             JMP loop
x           DAT #0      ; 1  2  4  8 16 32
count       DAT #5      ; 4  3  2  1 0 -1
zero        DAT #0
             end puzzle
```

15110 Principles of Computing,
Carnegie Mellon University - CORTINA

26

Example: Fahrenheit to Celsius

$$\text{cels} = (\text{fahr} - 32) * 5 / 9$$

```
fahr      DAT #82      ; fahrenheit value
cels      DAT #0       ; store result here
ftmp      DAT #0       ; save fahr-32 here
acc       DAT #0       ; accumulate answer
count     DAT #5       ; counter for mult.
```

(program continues on next page)

Example: Fahrenheit to Celsius

```
start      MOV fahr, ftmp      } set ftmp = fahr - 32
           SUB #32, ftmp
mult       ADD ftmp, acc       } add ftmp to acc
           SUB #1, count       } 5 times
           JMN mult, count     } (count starts off at 5)
div        SUB #9, acc        } divide acc by 9:
           SLT #0, acc         } subtract 9 from acc
           DAT #0 ; halt       } and add 1 to cels to
           ADD #1, cels        } see how many times
           JMP div             } 9 divides into acc
           end start          } always jump to
                                } label div
```

skip next instruction if 0 is less than acc
