

**15-213**

*"The course that gives CMU its Zip!"*

## Machine-Level Programming IV: Structured Data Sept. 19, 2002

### Topics

- Arrays
- Structs
- Unions

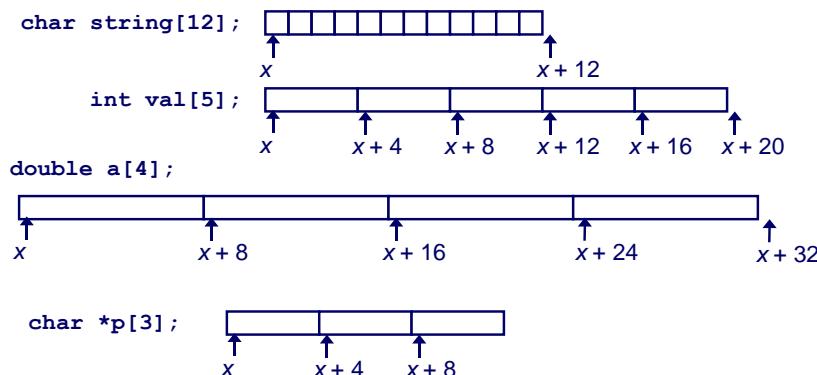

class08.ppt

15-213, F'02

## Array Allocation

### Basic Principle

- $T A[L];$
- Array of data type  $T$  and length  $L$
  - Contiguously allocated region of  $L * \text{sizeof}(T)$  bytes

- 3 -

15-213, F'02

## Basic Data Types

### Integral

- Stored & operated on in general registers
- Signed vs. unsigned depends on instructions used

Intel	GAS	Bytes	C
byte	b	1	[unsigned] char
word	w	2	[unsigned] short
double word	l	4	[unsigned] int

### Floating Point

- Stored & operated on in floating point registers

Intel	GAS	Bytes	C
Single	s	4	float
Double	l	8	double
Extended	t	10/12	long double

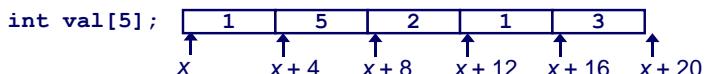

- 2 -

15-213, F'02

## Array Access

### Basic Principle

- $T A[L];$
- Array of data type  $T$  and length  $L$
  - Identifier  $A$  can be used as a pointer to array element 0

Reference	Type	Value
val[4]	int	3
val	int *	x
val+1	int *	x+4
&val[2]	int *	x+8
val[5]	int	??
*(val+1)	int	5
val + i	int *	x+4 i

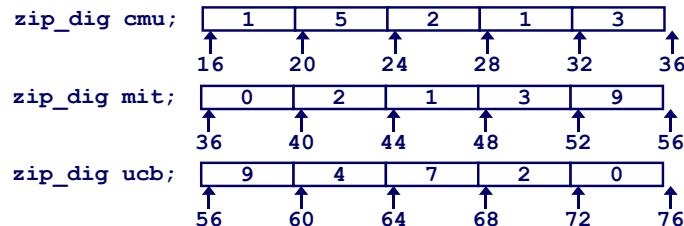

15-213, F'02

- 4 -

## Array Example

```
typedef int zip_dig[5];

zip_dig cmu = { 1, 5, 2, 1, 3 };
zip_dig mit = { 0, 2, 1, 3, 9 };
zip_dig ucb = { 9, 4, 7, 2, 0 };
```

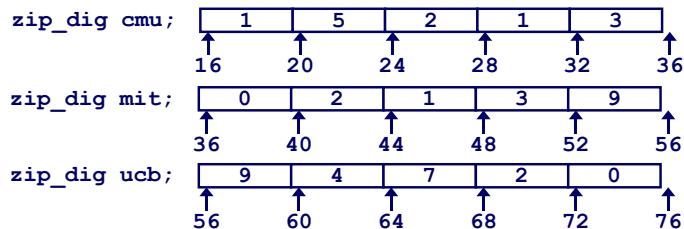

### Notes

- Declaration “`zip_dig cmu`” equivalent to “`int cmu[5]`”
- Example arrays were allocated in successive 20 byte blocks
  - Not guaranteed to happen in general

- 5 -

15-213, F'02

## Referencing Examples

Code Does Not Do Any Bounds Checking!

Reference	Address	Value	Guaranteed?
<code>mit[3]</code>	$36 + 4 * 3 = 48$	3	Yes
<code>mit[5]</code>	$36 + 4 * 5 = 56$	9	No
<code>mit[-1]</code>	$36 + 4 * -1 = 32$	3	No
<code>cmu[15]</code>	$16 + 4 * 15 = 76$	??	No

- Out of range behavior implementation-dependent
  - No guaranteed relative allocation of different arrays

- 7 -

15-213, F'02

## Array Accessing Example

### Computation

- Register `%edx` contains starting address of array
- Register `%eax` contains array index
- Desired digit at  $4 * %eax + %edx$
- Use memory reference `(%edx,%eax,4)`

```
int get_digit
  (zip_dig z, int dig)
{
    return z[dig];
}
```

### Memory Reference Code

```
# %edx = z
# %eax = dig
movl (%edx,%eax,4),%eax # z[dig]
```

- 6 -

15-213, F'02

## Array Loop Example

### Original Source

```
int zd2int(zip_dig z)
{
    int i;
    int zi = 0;
    for (i = 0; i < 5; i++) {
        zi = 10 * zi + z[i];
    }
    return zi;
}
```

### Transformed Version

- As generated by GCC
- Eliminate loop variable `i`
- Convert array code to pointer code
- Express in do-while form
  - No need to test at entrance

```
int zd2int(zip_dig z)
{
    int zi = 0;
    int *zend = z + 4;
    do {
        zi = 10 * zi + *z;
        z++;
    } while(z <= zend);
    return zi;
}
```

- 8 -

15-213, F'02

# Array Loop Implementation

## Registers

```
%ecx z
%eax zi
%ebx zend
```

## Computations

- $10 \cdot zi + *z$  implemented as  
 $*z + 2 \cdot (zi + 4 \cdot zi)$
- $z++$  increments by 4

```
int zd2int(zip_dig z)
{
    int zi = 0;
    int *zend = z + 4;
    do {
        zi = 10 * zi + *z;
        z++;
    } while(z <= zend);
    return zi;
}
```

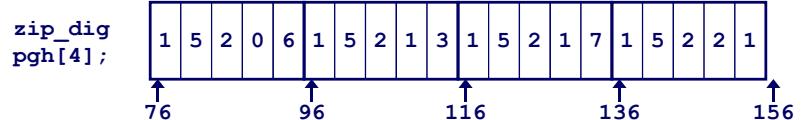

```
# %ecx = z
xorl %eax,%eax      # zi = 0
leal 16(%ecx),%ebx   # zend  = z+4
.L59:
    leal (%eax,%eax,4),%edx # 5*zi
    movl (%ecx),%eax        # *z
    addl $4,%ecx            # z++
    leal (%eax,%edx,2),%eax # zi = *z + 2*(5*zi)
    cmpl %ebx,%ecx          # z : zend
    jle .L59                # if <= goto loop
```

15-213, F'02

- 9 -

# Nested Array Example

```
#define PCOUNT 4
zip_dig pgh[PCOUNT] =
{{1, 5, 2, 0, 6},
 {1, 5, 2, 1, 3},
 {1, 5, 2, 1, 7},
 {1, 5, 2, 2, 1}};
```

- Declaration “zip\_dig pgh[4]” equivalent to “int pgh[4][5]”
  - Variable pgh denotes array of 4 elements
    - Allocated contiguously
  - Each element is an array of 5 int's
    - Allocated contiguously
- “Row-Major” ordering of all elements guaranteed

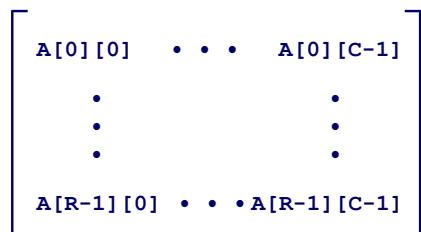

- 10 -

15-213, F'02

# Nested Array Allocation

## Declaration

- ```
T A[R][C];
```
- Array of data type  $T$
  - $R$  rows,  $C$  columns
  - Type  $T$  element requires  $K$  bytes

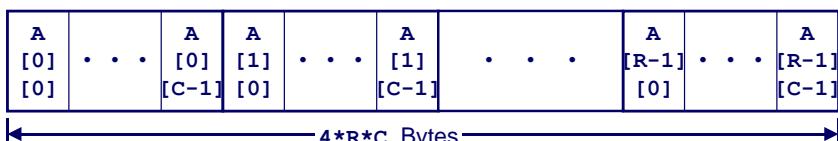

## Array Size

- $R \cdot C \cdot K$  bytes

## Arrangement

- Row-Major Ordering

```
int A[R][C];
```

- 11 -

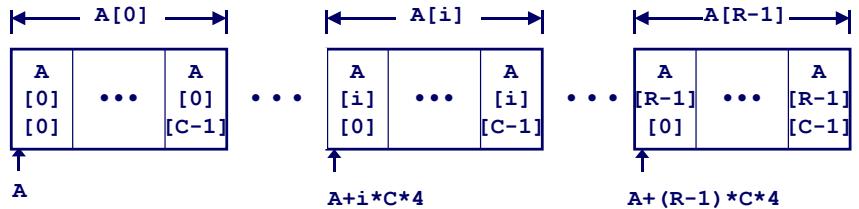

15-213, F'02

# Nested Array Row Access

## Row Vectors

- $A[i]$  is array of  $C$  elements
- Each element of type  $T$
- Starting address  $A + i \cdot C \cdot K$

```
int A[R][C];
```

- 12 -

15-213, F'02

## Nested Array Row Access Code

```
int *get_pgh_zip(int index)
{
    return pgh[index];
}
```

### Row Vector

- pgh[index] is array of 5 int's
- Starting address pgh+20\*index

### Code

- Computes and returns address
- Compute as pgh + 4\*(index+4\*index)

```
# %eax = index
leal (%eax,%eax,4),%eax # 5 * index
leal pgh(%eax,4),%eax # pgh + (20 * index)
```

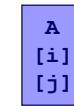

- 13 -

15-213, F'02

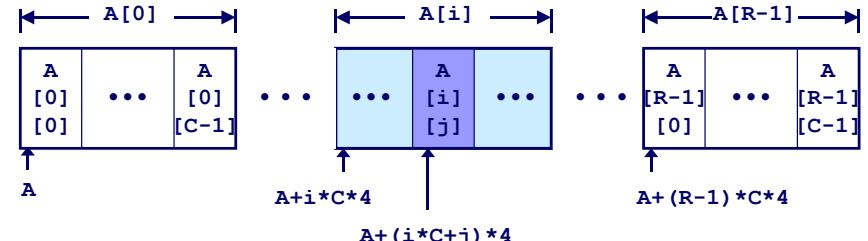

## Nested Array Element Access

### Array Elements

- A[i][j] is element of type T
- Address A + (i\*C + j)\*K

int A[R][C];

- 14 -

15-213, F'02

## Nested Array Element Access Code

### Array Elements

- pgh[index][dig] is int
- Address:  
pgh + 20\*index + 4\*dig

### Code

- Computes address  
pgh + 4\*dig + 4\*(index+4\*index)
- movl performs memory reference

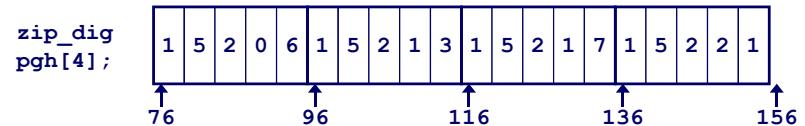

```
int get_pgh_digit
    (int index, int dig)
{
    return pgh[index][dig];
}
```

```
# %ecx = dig
# %eax = index
leal 0(%ecx,4),%edx      # 4*dig
leal (%eax,%eax,4),%eax # 5*index
movl pgh(%edx,%eax,4),%eax # *(pgh + 4*dig + 20*index)
```

- 15 -

15-213, F'02

## Strange Referencing Examples

### Reference Address Value Guaranteed?

| Reference  | Address            |    |     |
|------------|--------------------|----|-----|
| pgh[3][3]  | 76+20*3+4*3 = 148  | 2  | Yes |
| pgh[2][5]  | 76+20*2+4*5 = 136  | 1  | Yes |
| pgh[2][-1] | 76+20*2+4*-1 = 112 | 3  | Yes |
| pgh[4][-1] | 76+20*4+4*-1 = 152 | 1  | Yes |
| pgh[0][19] | 76+20*0+4*19 = 152 | 1  | Yes |
| pgh[0][-1] | 76+20*0+4*-1 = 72  | ?? | No  |

- Code does not do any bounds checking
- Ordering of elements within array guaranteed

- 16 -

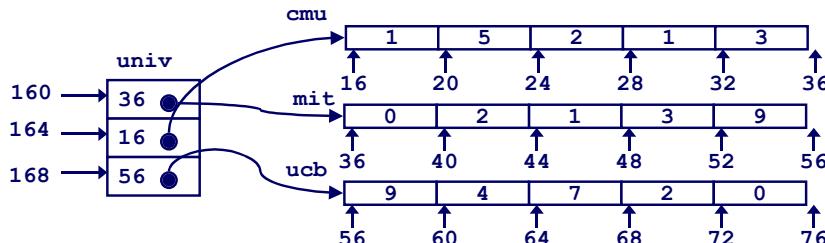

15-213, F'02

# Multi-Level Array Example

- Variable `univ` denotes array of 3 elements
- Each element is a pointer
  - 4 bytes
- Each pointer points to array of int's

```
zip_dig cmu = { 1, 5, 2, 1, 3 };
zip_dig mit = { 0, 2, 1, 3, 9 };
zip_dig ucb = { 9, 4, 7, 2, 0 };

#define UCOUNT 3
int *univ[UCOUNT] = {mit, cmu, ucb};
```

- 17 -

15-213, F'02

# Element Access in Multi-Level Array

```
int get_univ_digit
    (int index, int dig)
{
    return univ[index][dig];
}
```

## Computation

- Element access  
 $\text{Mem}[\text{Mem}[\text{univ}+4*\text{index}]+4*\text{dig}]$
- Must do two memory reads
  - First get pointer to row array
  - Then access element within array

```
# %ecx = index
# %eax = dig
leal 0(%ecx,4),%edx      # 4*index
movl univ(%edx),%edx     # Mem[univ+4*index]
movl (%edx,%eax,4),%eax # Mem[...+4*dig]
```

- 18 -

15-213, F'02

# Array Element Accesses

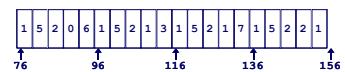

## ■ Similar C references

### Nested Array

```
int get_pgh_digit
    (int index, int dig)
{
    return pgh[index][dig];
}
```

## ■ Element at

$\text{Mem}[\text{pgh}+20*\text{index}+4*\text{dig}]$

- 19 -

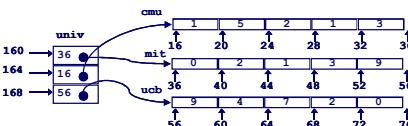

## ■ Different address computation

### Multi-Level Array

```
int get_univ_digit
    (int index, int dig)
{
    return univ[index][dig];
}
```

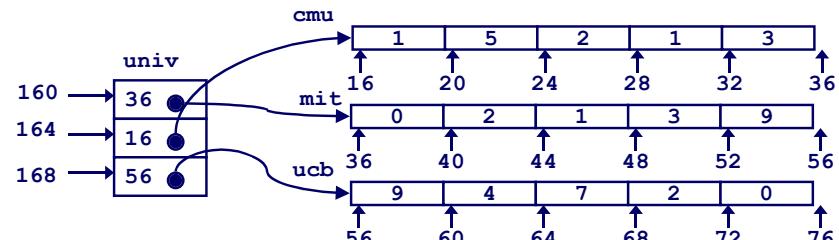

## ■ Element at

$\text{Mem}[\text{Mem}[\text{univ}+4*\text{index}]+4*\text{dig}]$

15-213, F'02

# Strange Referencing Examples

| Reference | Address | Value | Guaranteed? |
|-----------|---------|-------|-------------|
|-----------|---------|-------|-------------|

|             |                |    |     |
|-------------|----------------|----|-----|
| univ[2][3]  | $56+4*3 = 68$  | 2  | Yes |
| univ[1][5]  | $16+4*5 = 36$  | 0  | No  |
| univ[2][-1] | $56+4*-1 = 52$ | 9  | No  |
| univ[3][-1] | ??             | ?? | No  |
| univ[1][12] | $16+4*12 = 64$ | 7  | No  |

- Code does not do any bounds checking

- Ordering of elements in different arrays not guaranteed

- 20 -

15-213, F'02

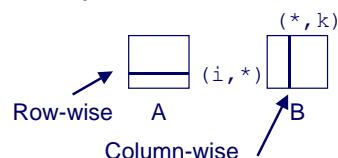

# Using Nested Arrays

## Strengths

- C compiler handles doubly subscripted arrays
- Generates very efficient code
  - Avoids multiply in index computation

## Limitation

- Only works if have fixed array size

- 21 -

```
#define N 16
typedef int fix_matrix[N][N];

/* Compute element i,k of
   fixed matrix product */
int fix_prod_ele
(fix_matrix a, fix_matrix b,
 int i, int k)
{
    int j;
    int result = 0;
    for (j = 0; j < N; j++)
        result += a[i][j]*b[j][k];
    return result;
}
```

15-213, F'02

# Dynamic Nested Arrays

## Strength

- Can create matrix of arbitrary size

## Programming

- Must do index computation explicitly

## Performance

- Accessing single element costly
- Must do multiplication

```
movl 12(%ebp),%eax      # i
movl 8(%ebp),%edx       # a
imull 20(%ebp),%eax    # n*i
addl 16(%ebp),%eax     # n*i+j
movl (%edx,%eax,4),%eax # Mem[a+4*(i*n+j)]
```

- 22 -

```
int * new_var_matrix(int n)
{
    return (int *)
        calloc(sizeof(int), n*n);
}
```

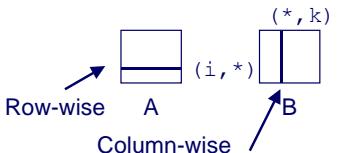

```
int var_ele
(int *a, int i,
 int j, int n)
{
    return a[i*n+j];
}
```

15-213, F'02

# Dynamic Array Multiplication

## Without Optimizations

- Multiplies
  - 2 for subscripts
  - 1 for data
- Adds
  - 4 for array indexing
  - 1 for loop index
  - 1 for data

- 23 -

```
/* Compute element i,k of
   variable matrix product */
int var_prod_ele
(int *a, int *b,
 int i, int k, int n)
{
    int j;
    int result = 0;
    for (j = 0; j < n; j++)
        result +=
            a[i*n+j] * b[j*n+k];
    return result;
}
```

15-213, F'02

# Optimizing Dynamic Array Mult.

## Optimizations

- Performed when set optimization level to -O2

## Code Motion

- Expression  $i*n$  can be computed outside loop

## Strength Reduction

- Incrementing  $j$  has effect of incrementing  $j*n+k$  by  $n$

## Performance

- Compiler can optimize regular access patterns

```
{
    int j;
    int result = 0;
    for (j = 0; j < n; j++)
        result +=
            a[i*n+j] * b[j*n+k];
    return result;
}

{
    int j;
    int result = 0;
    int iTn = i*n;
    int jTnPk = k;
    for (j = 0; j < n; j++) {
        result +=
            a[iTn+j] * b[jTnPk];
        jTnPk += n;
    }
    return result;
}
```

- 24 -

# Structures

## Concept

- Contiguously-allocated region of memory
- Refer to members within structure by names
- Members may be of different types

```
struct rec {  
    int i;  
    int a[3];  
    int *p;  
};
```

Memory Layout

## Accessing Structure Member

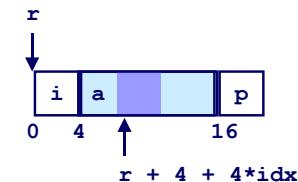

```
void  
set_i(struct rec *r,  
      int val)  
{  
    r->i = val;  
}
```

Assembly

```
# %eax = val  
# %edx = r  
movl %eax,(%edx)    # Mem[r] = val
```

- 25 -

15-213, F'02

# Generating Pointer to Struct. Member

```
struct rec {  
    int i;  
    int a[3];  
    int *p;  
};
```

## Generating Pointer to Array Element

- Offset of each structure member determined at compile time

```
int *  
find_a  
(struct rec *r, int idx)  
{  
    return &r->a[idx];  
}
```

```
# %ecx = idx  
# %edx = r  
leal 0(%ecx,4),%eax    # 4*idx  
leal 4(%eax,%edx),%eax # r+4*idx+4
```

- 26 -

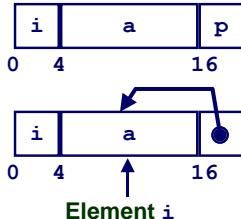

15-213, F'02

# Structure Referencing (Cont.)

## C Code

```
struct rec {  
    int i;  
    int a[3];  
    int *p;  
};
```

```
void  
set_p(struct rec *r)  
{  
    r->p =  
        &r->a[r->i];  
}
```

```
# %edx = r  
movl (%edx),%ecx      # r->i  
leal 0(%ecx,4),%eax   # 4*(r->i)  
leal 4(%edx,%eax),%eax # r+4+4*(r->i)  
movl %eax,16(%edx)    # Update r->p
```

- 27 -

15-213, F'02

# Alignment

## Aligned Data

- Primitive data type requires K bytes
- Address must be multiple of K
- Required on some machines; advised on IA32
  - treated differently by Linux and Windows!

## Motivation for Aligning Data

- Memory accessed by (aligned) double or quad-words
  - Inefficient to load or store datum that spans quad word boundaries
  - Virtual memory very tricky when datum spans 2 pages

## Compiler

- Inserts gaps in structure to ensure correct alignment of fields

- 28 -

15-213, F'02

# Specific Cases of Alignment

## Size of Primitive Data Type:

- **1 byte (e.g., char)**
  - no restrictions on address
- **2 bytes (e.g., short)**
  - lowest 1 bit of address must be 0<sub>2</sub>
- **4 bytes (e.g., int, float, char \*, etc.)**
  - lowest 2 bits of address must be 00<sub>2</sub>
- **8 bytes (e.g., double)**
  - Windows (and most other OS's & instruction sets):
    - » lowest 3 bits of address must be 000<sub>2</sub>
  - Linux:
    - » lowest 2 bits of address must be 00<sub>2</sub>
    - » i.e., treated the same as a 4-byte primitive data type
- **12 bytes (long double)**
  - Linux:
    - » lowest 2 bits of address must be 00<sub>2</sub>
    - » i.e., treated the same as a 4-byte primitive data type

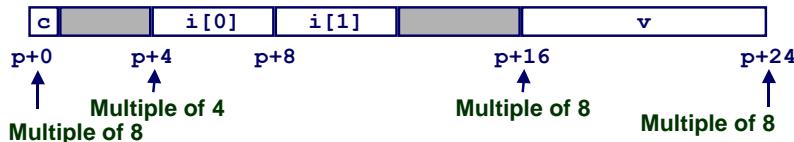

- 29 -

15-213, F'02

# Linux vs. Windows

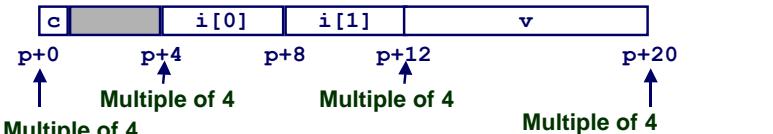

## Windows (including Cygwin):

- K = 8, due to double element

## Linux:

- K = 4; double treated like a 4-byte data type

- 31 -

15-213, F'02

# Satisfying Alignment with Structures

## Offsets Within Structure

- Must satisfy element's alignment requirement

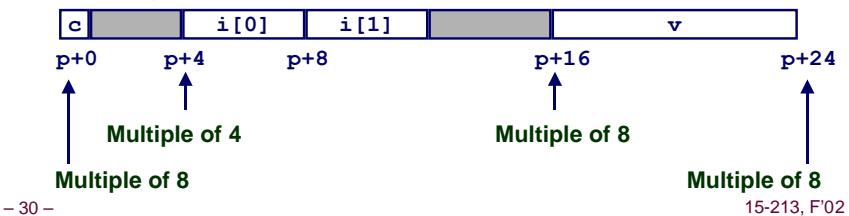

## Overall Structure Placement

- Each structure has alignment requirement K
  - Largest alignment of any element
- Initial address & structure length must be multiples of K

```
struct S1 {
    char c;
    int i[2];
    double v;
} *p;
```

## Example (under Windows):

- K = 8, due to double element

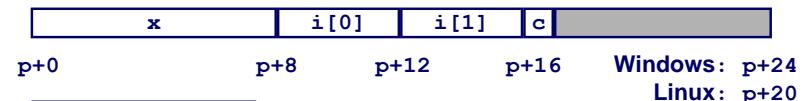

- 30 -

15-213, F'02

# Overall Alignment Requirement

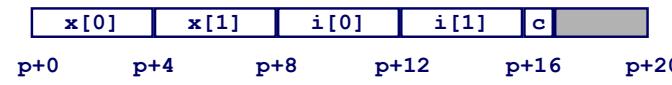

```
struct S2 {
    double x;
    int i[2];
    char c;
} *p;
```

p must be multiple of:  
8 for Windows  
4 for Linux

```
struct S3 {
    float x[2];
    int i[2];
    char c;
} *p;
```

p must be multiple of 4 (in either OS)

- 32 -

15-213, F'02

## Ordering Elements Within Structure

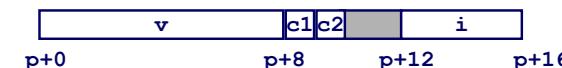

```
struct S4 {
    char c1;
    double v;
    char c2;
    int i;
} *p;
```

10 bytes wasted space in Windows

```
struct S5 {
    double v;
    char c1;
    char c2;
    int i;
} *p;
```

2 bytes wasted space

- 33 -

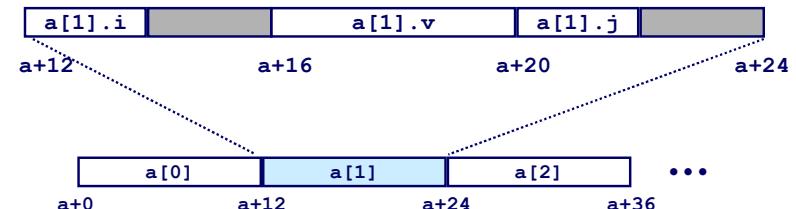

15-213, F'02

## Arrays of Structures

### Principle

- Allocated by repeating allocation for array type
- In general, may nest arrays & structures to arbitrary depth

```
struct S6 {
    short i;
    float v;
    short j;
} a[10];
```

- 34 -

15-213, F'02

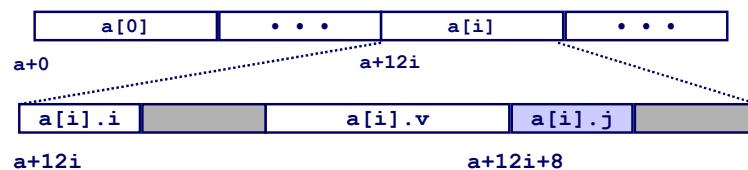

## Accessing Element within Array

- Compute offset to start of structure
  - Compute  $12 \cdot i$  as  $4 \cdot (i+2)$
- Access element according to its offset within structure
  - Offset by 8
  - Assembler gives displacement as  $a + 8$ 
    - » Linker must set actual value

```
struct S6 {
    short i;
    float v;
    short j;
} a[10];
```

```
short get_j(int idx)
{
    return a[idx].j;
}
```

```
# %eax = idx
leal (%eax,%eax,2),%eax # 3*idx
movswl a+8(%eax,4),%eax
```

- 35 -

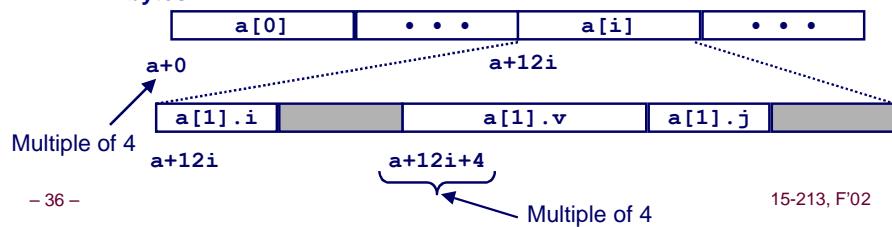

15-213, F'02

## Satisfying Alignment within Structure

### Achieving Alignment

- Starting address of structure array must be multiple of worst-case alignment for any element
  - a must be multiple of 4
- Offset of element within structure must be multiple of element's alignment requirement
  - v's offset of 4 is a multiple of 4
- Overall size of structure must be multiple of worst-case alignment for any element
  - Structure padded with unused space to be 12 bytes

```
struct S6 {
    short i;
    float v;
    short j;
} a[10];
```

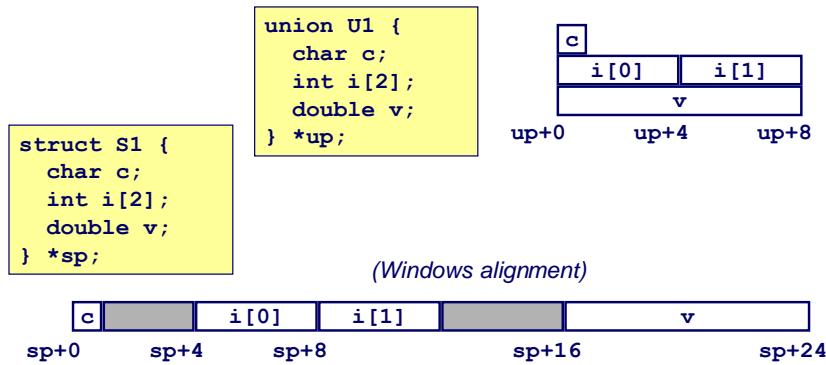

- 36 -

15-213, F'02

# Union Allocation

## Principles

- Overlay union elements
- Allocate according to largest element
- Can only use one field at a time

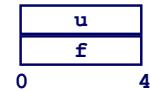

- 37 -

15-213, F'02

# Using Union to Access Bit Patterns

```
typedef union {
    float f;
    unsigned u;
} bit_float_t;
```

```
float bit2float(unsigned u)
{
    bit_float_t arg;
    arg.u = u;
    return arg.f;
}
```

```
unsigned float2bit(float f)
{
    bit_float_t arg;
    arg.f = f;
    return arg.u;
}
```

- Get direct access to bit representation of float
- `bit2float` generates float with given bit pattern
  - NOT the same as `(float) u`
- `float2bit` generates bit pattern from float
  - NOT the same as `(unsigned) f`

- 38 -

15-213, F'02

# Byte Ordering Revisited

## Idea

- Short/long/quad words stored in memory as 2/4/8 consecutive bytes
- Which is most (least) significant?
- Can cause problems when exchanging binary data between machines

## Big Endian

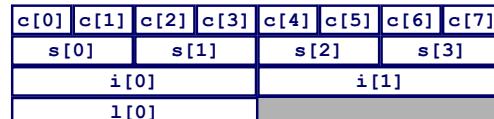

- Most significant byte has lowest address
- PowerPC, Sparc

## Little Endian

- Least significant byte has lowest address
- Intel x86, Alpha

# Byte Ordering Example

```
union {
    unsigned char c[8];
    unsigned short s[4];
    unsigned int i[2];
    unsigned long l[1];
} dw;
```

- 39 -

15-213, F'02

- 40 -

15-213, F'02

## Byte Ordering Example (Cont.)

```

int j;
for (j = 0; j < 8; j++)
dw.c[j] = 0xf0 + j;

printf("Characters 0-7 ==\n"
[0x%x,0x%x,0x%x,0x%x,0x%x,0x%x,0x%x]\n",
dw.c[0], dw.c[1], dw.c[2], dw.c[3],
dw.c[4], dw.c[5], dw.c[6], dw.c[7]);

printf("Shorts 0-3 ==\n"
[0x%x,0x%x,0x%x,0x%x]\n",
dw.s[0], dw.s[1], dw.s[2], dw.s[3]);

printf("Ints 0-1 == [0x%x,0x%x]\n",
dw.i[0], dw.i[1]);

printf("Long 0 == [0x%lx]\n",
dw.l[0]);

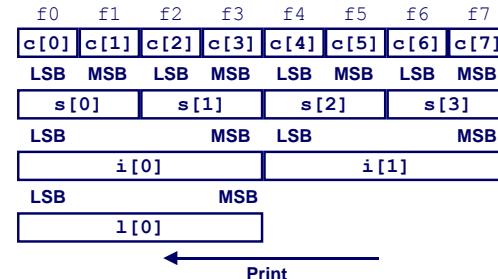

```

- 41 -

15-213, F'02

## Byte Ordering on x86

### Little Endian

### Output on Pentium:

```

Characters 0-7 == [0xf0,0xf1,0xf2,0xf3,0xf4,0xf5,0xf6,0xf7]
Shorts    0-3 == [0xf1f0,0xf3f2,0xf5f4,0xf7f6]
Ints      0-1 == [0xf3f2f1f0,0xf7f6f5f4]
Long       0 == [f3f2f1f0]

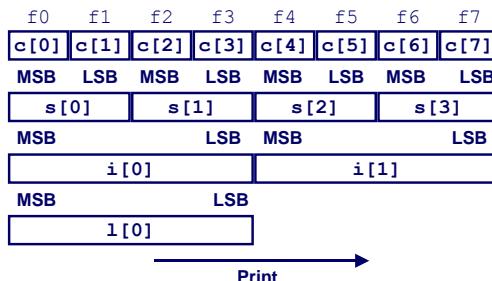

```

- 42 -

15-213, F'02

## Byte Ordering on Sun

### Big Endian

### Output on Sun:

```

Characters 0-7 == [0xf0,0xf1,0xf2,0xf3,0xf4,0xf5,0xf6,0xf7]
Shorts    0-3 == [0xf0f1,0xf2f3,0xf4f5,0xf6f7]
Ints      0-1 == [0xf0f1f2f3,0xf4f5f6f7]
Long       0 == [0xf0f1f2f3]

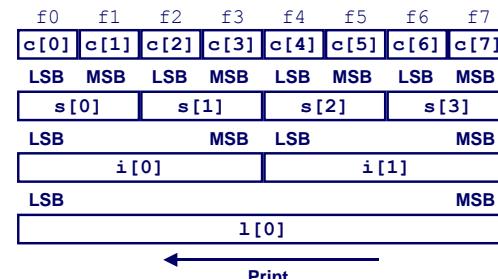

```

# Summary

## Arrays in C

- Contiguous allocation of memory
- Pointer to first element
- No bounds checking

## Compiler Optimizations

- Compiler often turns array code into pointer code (`zd2int`)
- Uses addressing modes to scale array indices
- Lots of tricks to improve array indexing in loops

## Structures

- Allocate bytes in order declared
- Pad in middle and at end to satisfy alignment

## Unions

- Overlay declarations
- Way to circumvent type system
