- The need for synchronization
- Synchronizing with semaphores
- Thread safety and reentrancy
- Races and deadlocks

Shared Variables in Threaded C Programs

Question: Which variables in a threaded C program are shared variables?
- The answer is not as simple as "global variables are shared" and "stack variables are private".

Requires answers to the following questions:
- What is the memory model for threads?
- How are variables mapped to memory instances?
- How many threads reference each of these instances?

Threads Memory Model

Conceptual model:
- Each thread runs in the context of a process.
- Each thread has its own separate thread context.
- Thread ID, stack, stack pointer, program counter, condition codes, and general purpose registers.
- All threads share the remaining process context.
- Code, data, heap, and shared library segments of the process virtual address space.
- Open files and system handlers

Operationally, this model is not strictly enforced:
- While register values are truly separate and protected... Any thread can read and write the stack of any other thread.

Mismatch between the conceptual and operation model is a source of confusion and errors.

Example of Threads Accessing Another Thread’s Stack

char *ptr; /* global */
int main()
{
    int i;
    pthread_t tid;
    char *msg[i] = {
        "Hello from foo",
        "Hello from bar"
    };
    ptr = msg;
    for (i = 0; i < 2; i++)
        pthread_create(&tid, NULL, thread, (void *)&i);
    pthread_exit(NULL);

    /* thread routine */
    void *thread(void *vargp)
    {
        int myid = (int)vargp;
        static int var = 0;
        printf("Hi [%d]: %s\n", myid, ptr[myid], ++var);
    }

Peer threads access main thread’s stack indirectly through global ptr variable.
Mapping Variables to Mem. Instances

Global var: instance ptr [data]
Local automatic var: 1 instance (l.m. masts m)
char *ptr; /* global */
int main()
{
    int i;
    pthread_t tid;
    char *masts(m) = "Hello from foo."
    "Hello from bar";
    ptr = masts;
    for (i = 0; i < 2; i++)
        Pthread_create(tid, NULL,
        thread, (void *)&i);
    pthread_exit(NULL);
}

Local automatic var: 2 instances (myid.p1 [peer thread 1's stack])

/* thread routine */
void *thread(void *argp)
{
    int myid = (int)argp;
    static int ovar = 0;
    printf("(tid): %s (_argv):%d", myid, ptr[myid], oswar);
}

Local static var: 1 instance (ovar [data])

Shared Variable Analysis

Which variables are shared?

<table>
<thead>
<tr>
<th>Variable</th>
<th>Referenced by main thread?</th>
<th>Referenced by peer thread?</th>
<th>Referenced by peer thread ??</th>
</tr>
</thead>
<tbody>
<tr>
<td>ptr</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
</tr>
<tr>
<td>ovar</td>
<td>no</td>
<td>yes</td>
<td>no</td>
</tr>
<tr>
<td>l.m. masts</td>
<td>yes</td>
<td>no</td>
<td>yes</td>
</tr>
<tr>
<td>myid.p1</td>
<td>no</td>
<td>no</td>
<td>yes</td>
</tr>
</tbody>
</table>

Answer: A variable x is shared iff multiple threads reference at least one instance of x. Thus:
- ptr, ovar, and masts are shared.
- l.m. and myid are NOT shared.

badent.c: An Improperly Synchronized Threaded Program

unsigned int cnt = 0; /* shared */
int main()
{
    pthread_t tid1, tid2;
    Pthread_create(tid1, NULL, count, NULL);
    Pthread_create(tid2, NULL, count, NULL);
    Pthread_join(tid1, NULL);
    Pthread_join(tid2, NULL);
    if (cnt != (unsigned)INT_MAX/2)
        printf("BAD! cnt=%d\n", cnt);
    else
        printf("OK! cnt=%d\n", cnt);
}

/* thread routine */
void *thread(void *argp)
{
    int i;
    for (i=0; i<INT_MAX/2; i++)
        cnt++;
    return NULL;
}

Assembly Code for Counter Loop

C code for counter loop

For (i=0; i<INT_MAX/2; i++)
cnt++;

Corresponding asm code

(gcc -00 -fforce-mem)

Head (H)

Load cnt (L)
Update cnt (U)
Store cnt (S)

Tail (T)

<table>
<thead>
<tr>
<th>C code</th>
<th>Corresponding asm code</th>
</tr>
</thead>
<tbody>
<tr>
<td>L:</td>
<td>movl -4(tbp), %eax</td>
</tr>
<tr>
<td></td>
<td>cmpl 99999999, %eax</td>
</tr>
<tr>
<td></td>
<td>jle 111</td>
</tr>
<tr>
<td></td>
<td>jmp 110</td>
</tr>
<tr>
<td></td>
<td>nolst cnt, %eax</td>
</tr>
<tr>
<td></td>
<td>movl 1(%eax), %edx</td>
</tr>
<tr>
<td></td>
<td>leal 1(%eax), %edx</td>
</tr>
<tr>
<td></td>
<td>movl %edx, %eax</td>
</tr>
<tr>
<td></td>
<td>movl -4(tbp), %eax</td>
</tr>
<tr>

<td>leal 1(%eax), %edx</td>
</tr>
<tr>
<td></td>
<td>movl %edx, %eax</td>
</tr>
<tr>
<td></td>
<td>tail -7</td>
</tr>
</tbody>
</table>
Concurrent Execution

Key idea: In general, any sequentially consistent interleaving is possible, but some are incorrect!
- \( i \) denotes that thread \( i \) executes instruction \( i \)
- \( %eax \) is the contents of \( %eax \) in thread \( i \)'s context

<table>
<thead>
<tr>
<th>(thread)</th>
<th>instr ( i )</th>
<th>( %eax ) ( i )</th>
<th>( %eax )</th>
<th>cnt</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>( H_1 )</td>
<td>-</td>
<td>-</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>( U_1 )</td>
<td>0</td>
<td>-</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>( B_1 )</td>
<td>1</td>
<td>-</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>( H_2 )</td>
<td>-</td>
<td>-</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>( U_2 )</td>
<td>-</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>( S_2 )</td>
<td>-</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>( T_1 )</td>
<td>1</td>
<td>-</td>
<td>2</td>
</tr>
</tbody>
</table>

OK

Concurrent Execution (cont)

Incorrect ordering: two threads increment the counter, but the result is 1 instead of 2.

<table>
<thead>
<tr>
<th>(thread)</th>
<th>instr ( i )</th>
<th>( %eax )</th>
<th>( %eax )</th>
<th>cnt</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>( H_1 )</td>
<td>-</td>
<td>-</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>( U_1 )</td>
<td>0</td>
<td>-</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>( B_1 )</td>
<td>1</td>
<td>-</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>( H_2 )</td>
<td>-</td>
<td>-</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>( T_1 )</td>
<td>1</td>
<td>-</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>( T_2 )</td>
<td>-</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

Oops!

Concurrent Execution (cont)

How about this ordering?

<table>
<thead>
<tr>
<th>(thread)</th>
<th>instr ( i )</th>
<th>( %eax ) ( i )</th>
<th>( %eax )</th>
<th>cnt</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>( H_1 )</td>
<td>-</td>
<td>-</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>( U_1 )</td>
<td>0</td>
<td>-</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>( B_1 )</td>
<td>1</td>
<td>-</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>( H_2 )</td>
<td>-</td>
<td>-</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>( U_2 )</td>
<td>-</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>( S_2 )</td>
<td>-</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>( T_1 )</td>
<td>1</td>
<td>-</td>
<td>2</td>
</tr>
</tbody>
</table>

We can clarify our understanding of concurrent execution with the help of the progress graph

Progress Graphs

A progress graph depicts the discrete execution state space of concurrent threads.

Each axis corresponds to the sequential order of instructions in a thread.

Each point corresponds to a possible execution state (Instr., Inst.).

E.g., \((L_1, S_2)\) denotes state where thread 1 has completed \( L_1 \) and thread 2 has completed \( S_2 \).
**Trajectories in Progress Graphs**

**Def:** A trajectory is safe iff it doesn’t touch any part of an unsafe region.

**Claim:** A trajectory is correct (wrt cnt) iff it is safe.

**Example:**
H1, L1, U1, H2, L2, S1, T1, U2, S2, T2

**Critical Sections and Unsafe Regions**

L, U, and S form a critical section with respect to the shared variable cnt.

Instructions in critical sections (wrt to some shared variable) should not be interleaved.

Sets of states where such interleaving occurs form unsafe regions.

**Safe and Unsafe Trajectories**

**Semaphores**

**Question:** How can we guarantee a safe trajectory?

- We must synchronize the threads so that they never enter an unsafe state.

**Classic solution: Dijkstra’s P and V operations on semaphores.**

- **semaphore**: non-negative integer synchronization variable.
  - P(s): while (s >= 0) wait(); s--;
  - Dutch for “Proberen” (test)
  - V(s): ++s;
  - Dutch for “Verhogen” (increment)

- OS guarantees that operations between brackets [ ] are executed indivisibly.
- Only one P or V operation at a time can modify s.
- When while loop in P terminates, only that P can decrement s.

**Semaphore invariant: (s >= 0)**
**Safe Sharing with Semaphores**

Here is how we would use P and V operations to synchronize the threads that update *cnt*.

```c
/* Semaphore s is initially 1 */
/* Thread routine */
void *count(void *arg)
{
    int i;
    for (i=0; i<ITEMS; i++)
    {
        cnt++;
        V(s);
    }
    return NULL;
}
```

**POSIX Semaphores**

```c
// Initialize semaphore sem to value /*
// pshared=0 if thread, pshared=1 if process */
void sem_init(sem_t *sem, int pshared, unsigned int value) {
    sem_error("sem_init");
}

// P operation on semaphore sem */
void P(sem_t *sem) {
    if (sem_wait(sem))
        sem_error("P");
}

// V operation on semaphore sem */
void V(sem_t *sem) {
    if (sem_post(sem))
        sem_error("V");
}
```

**Sharing With POSIX Semaphores**

```c
// goodcnt.c - properly sync'd counter program */
#include "semph.h"
#define ITEMES 10000000

unsigned int cnt; /* counter */
sem_t sem; /* semaphore */

test main() {
    thread_t tid1, tid2;
    sem_init(sem, 0, 1); /* sem1 */
    /* create 2 threads and wait */
    ...
    if (cnt != (unsigned)ITEMES*2)
        printf("BOOM! cnt=%d\n", cnt);
    else
        printf("OK cnt=%d\n", cnt);
    exit(0);
}
```

**Safe Sharing With Semaphores**

Provide mutually exclusive access to shared variable by surrounding critical section with P and V operations on semaphore *s* (initially set to 1).

Semaphore invariant creates a forbidden region that encloses unsafe region and is never touched by any trajectory.
Signaling With Semaphores

Common synchronization pattern:
- Producer waits for slot, inserts item in buffer, and "signals" consumer.
- Consumer waits for item, removes it from buffer, and "signals" producer.
- "signals" in this context has nothing to do with Unix signals.

Examples:
- Multimedia processing: Producer creates MPEG video frames, consumer renders the frames.
- Event-driven graphical user interfaces: Producer detects mouse clicks, mouse movements, and keyboard hits and inserts corresponding events in buffer.
- Consumer retrieves events from buffer and paints the display.

---

Producer-Consumer on a Buffer That Holds One Item

```c
int main() {
    pthread_t tid_producer;
    pthread_t tid_consumer;
    
    /* initialize the semaphores */
    Sem_init(Shmem.empty, 0, 1);
    Sem_init(Shmem.full, 0, 0);
    
    /* create threads and wait */
    pthread_create(tid_producer, NULL, producer, NULL);
    pthread_create(tid_consumer, NULL, consumer, NULL);
    pthread_join(tid_producer, NULL);
    pthread_join(tid_consumer, NULL);
    wait(0);
}
```

---

Producer-Consumer (cont)

Initially: empty = 1, full = 0.

```c
// producer thread */
void *producer(void *arg) {
    int i, item;
    for (i=0; i<NUM_ITEMS; i++) {
        // produce item */
        item = i;
        printf("produced %d
", item);
        // write item to buf */
        shared.buf = item;
        V(Shmem.empty);
    } return NULL;
}
```

```c
// consumer thread */
void *consumer(void *arg) {
    int i, item;
    for (i=0; i<NUM_ITEMS; i++) {
        // read item from buf */
        P(Shmem.full);
        item = shared.buf;
        V(Shmem.empty);
        // consume item */
        printf("consumed %d
", item);
    } return NULL;
}
```

---

Thread Safety

Functions called from a thread must be thread-safe.

We identify four (non-disjoint) classes of thread-unsafe functions:
- Class 1: Failing to protect shared variables.
- Class 2: Relying on persistent state across invocations.
- Class 3: Returning a pointer to a static variable.
- Class 4: Calling thread-unsafe functions.
Thread-Unsafe Functions

Class 1: Failing to protect shared variables.
- Fix: Use P and V semaphore operations.
- Issue: Synchronization operations will slow down code.
- Example: goodcnt.c

---

Thread-Unsafe Functions (cont)

Class 2: Relying on persistent state across multiple function invocations.
- Fix: Rewrite function so that caller passes in all necessary state.

```c
/* rand - return pseudo-random integer on 0..32767 */
int rand(void)
{
    static unsigned int next = 1;
    next = next*1103515245 % 2147483647;
    return (unsigned int)(next/65536) % 32768;
}
/* srand - set seed for rand() */
void srand(unsigned int seed)
{
    next = seed;
}
```

---

Thread-Unsafe Functions (cont)

Class 3: Returning a ptr to a static variable.
Fixes:
- 1. Rewrite code so caller passes pointer to struct.
   - Issue: Requires changes in caller and callee.
- 2. Lock-and-copy
   - Issue: Requires only simple changes in caller (and none in callee)
   - However, caller must free memory.

```c
struct hostent
+gethostbyname(char name)
{
    static struct hostent h;
    <contact DNS and fill in h>
    return h;
}
hostent = malloc(...);
gethostbyname p(name, hostent);
```

---

Thread-Unsafe Functions

Class 4: Calling thread-unsafe functions.
- Fix: Modify the function so it calls only thread-safe functions

```c
struct hostent
+gethostbyname_ptr(char *p)
{
    struct hostent *q = malloc(...);
    P(q); /* look */
    p = gethostbyname(name);
    *q = p; /* copy */
    Y(q); /* */
    return q;
}
```
Reentrant Functions

A function is reentrant if it accesses no shared variables when called from multiple threads. Reentrant functions are a proper subset of the set of thread-safe functions.

**NOTE:** The fix to Class 2 and 3 thread-unsafe functions require modifying the function to make it reentrant.

---

Thread-Safe Library Functions

All functions in the Standard C Library (at the back of your K&R text) are thread-safe.

- Examples: malloc, free, printf, scanf

Most Unix system calls are thread-safe, with a few exceptions:

<table>
<thead>
<tr>
<th>Thread-unsafe function</th>
<th>Class</th>
<th>Reentrant version</th>
</tr>
</thead>
<tbody>
<tr>
<td>acctime</td>
<td>3</td>
<td>acctime_r</td>
</tr>
<tr>
<td>strftime</td>
<td>3</td>
<td>strftime_r</td>
</tr>
<tr>
<td>gethostbyaddr</td>
<td>3</td>
<td>gethostbyaddr_r</td>
</tr>
<tr>
<td>gethostbyname</td>
<td>3</td>
<td>gethostbyname_r</td>
</tr>
<tr>
<td>inet_ptrna</td>
<td>3</td>
<td>(none)</td>
</tr>
<tr>
<td>localtime</td>
<td>3</td>
<td>localtime_r</td>
</tr>
<tr>
<td>rand</td>
<td>2</td>
<td>rand_r</td>
</tr>
</tbody>
</table>

---

Races

A race occurs when the correctness of the program depends on one thread reaching point x before another thread reaches point y.

```c
// a threaded program with a race */
int main() {
    pthread_t tid[N];
    int i;
    for (i = 0; i < N; i++)
        pthread_create(&tid[i], NULL, thread, (void *)&i);
    for (i = 0; i < N; i++)
        pthread_join(tid[i], NULL);
    exit(0);
}

/* thread routine */
void *thread(void *vargs) {
    int myid = *((int *)vargs);
    printf("Hello from thread %d\n", myid);
    return NULL;
}
```

---

Deadlock

Locking introduces the potential for deadlock: waiting for a condition that will never be true.

Any trajectory that enters the deadlock region will eventually reach the deadlock state, waiting for either s or t to become nonzero.

Other trajectories lock out and skirt the deadlock region.

Unfortunately, deadlock is often non-deterministic.
User Level Multi Threading

Pro’s and Cons for user level multithreading
- Pro: Fast, low overhead
- Pro: Scheduling can be controlled by user process
- Con: error prone (stack-overflow)
- Con: no seamless MP support

Co-routines, cooperative (non-preemptive) scheduling
POSIX Threads use the 1:1 model where 1 thread is 1 kernel scheduled entity.
M:N is a hybrid where M user-level threads use N kernel scheduled threads, to be added to NPTL
M:1 Thread libraries: GNU Pth, FSU Pthreads, MIT Pthreads, ...

How to Program Semaphores

Don’t: rely on libraries

Use message passing systems (PVM, MPI)

Exploit the memory model:
- Dekker’s Algorithm requires sequential consistency (SC)
- Other Algorithms exist for weaker memory models

Use atomic instructions
- Test&set
- Swap
- Load-locked / Store-conditional
- Compare & Swap
- Fetch&Op (exotic, rarely available)

Threads Summary

Threads provide another mechanism for writing concurrent programs.

Threads are growing in popularity
- Somewhat cheaper than processes.
- Easy to share data between threads.

However, the ease of sharing has a cost:
- Easy to introduce subtle synchronization errors.
- Tread carefully with threads!

For more info:
