Andrew login ID: ____________________________
Full Name: ________________________________

CS 15-213, Spring 2003

Exam 1
February 27, 2003

Instructions:

• Make sure that your exam is not missing any sheets, then write your full name and Andrew login ID on the front.

• Write your answers in the space provided below the problem. If you make a mess, clearly indicate your final answer.

• The exam has a maximum score of 60 points.

• The problems are of varying difficulty. The point value of each problem is indicated. Pile up the easy points quickly and then come back to the harder problems.

• This exam is OPEN BOOK. You may use any books or notes you like. No electronic devices are allowed. Good luck!

Problem 1. (1 points):
The correct answer to this problem is worth 1 point. An incorrect answer is worth -2 points. No answer will be scored as 0 points. Note: The answer to this question was given in lecture.
The correct answer to this problem is: ____________
Problem 2. (9 points):
Assume we are running code on an 8-bit machine using two’s complement arithmetic for signed integers. Short integers are encoded using 4 bits. Sign extension is performed whenever a short is casted to an int. For this problem, assume that all shift operations are arithmetic. Fill in the empty boxes in the table below.

```c
int i = -11;
unsigned ui = i;
short s = -2;
unsigned short us = s;
```

Note: You need not fill in entries marked with "–". TMax denotes the largest positive two’s complement number and Tmin denotes the minimum negative two’s complement number. Finally, you may use hexadecimal notation for your answers in the “Binary Representation” column.

Problem 3. (8 points):
Consider the following 7-bit floating point representation based on the IEEE floating point format:

- There is a sign bit in the most significant bit.
- The next 3 bits are the exponent. The exponent bias is 3.
- The last 3 bits are the fraction.
- The representation encodes numbers of the form: \( V = (-1)^s \times M \times 2^E \), where \( M \) is the significand and \( E \) the integer value of the exponent.

Please fill in the table below. You do not have to fill in boxes with "——" in them. If a number is NaN or infinity, you may disregard the \( M \), \( E \), and \( V \) fields below. However, fill the Description and Binary fields with valid data.

Here are some guidelines for each field:

- **Description** - A verbal description if the number has a special meaning
- **Binary** - Binary representation of the number
- **\( M \)** - Significand (same as the \( M \) in the formula above)
- **\( E \)** - Exponent (same as the \( E \) in \( 2^E \))
- **\( V \)** - Fractional Value represented

Please fill the \( M \), \( E \), and \( V \) fields below with rational numbers (fractions) rather than decimals or binary decimals.

<table>

Problem 4. (4 points):

Consider the following assembly instructions and C functions:

```
080483b4 <funcX>:
  80483b4:  55          push  %ebp
  80483b5:  89 e5       mov  %esp,%ebp
  80483b7:  8b 45 08    mov  0x8(%ebp),%eax
  80483ba:  8d 04 80    lea  (%eax,%eax,4),%eax
  80483bd:  8d 04 85 ff ff ff    lea  0xffffffff6(,%eax,4),%eax
  80483c4:  89 ec       mov  %ebp,%esp
  80483c6:  5d          pop  %ebp
  80483c7:  c3          ret
```

Circle the C function below that generates the above assembly instructions:

```c
int func1(int n) {
    return n * 20 - 10;
}

int func2(int n) {
    return n * 24 + 6;
}

int func3(int n) {
    return n * 16 - 4;
}
```
Problem 5. (8 points):
Consider the following pairs of C functions and assembly code. Draw a line connecting each C function with the block(s) of assembly code that implements it. There is not necessarily a one-to-one correspondence. Draw an X through any C and/or assembly code fragments that don’t have a match.

```c
int scooby(int *a)
{
    return a[4];
}
pushl %ebp
movl %esp, %ebp
movl 8(%ebp), %eax
sall $2, %eax
popl %ebp
ret
```

```c
int dooby(int a)
{
    return a*4;
}
pushl %ebp
movl %esp, %ebp
movl 8(%ebp), %eax
movsbl 4(%eax),%eax
popl %ebp
ret
```

```c
int doo(int a)
{
    return a<<4;
}
pushl %ebp
movl %esp, %ebp
movl 8(%ebp), %eax
sall $4, %eax
popl %ebp
ret
```

```c
char scrappy(char *a)
{
    return a[4];
}
pushl %ebp
movl %esp, %ebp
movl 8(%ebp), %eax
leal 0(%eax,4), %eax
popl %ebp
ret
```
Problem 6. (12 points):
Recently, Microsoft’s SQL Server was hit by the SQL Slammer worm, which exploits a known buffer overflow in the SQL Resolution Service. Today, we’ll be writing our own 213 Slammer that exploits the vulnerability introduced in bufbomb, the executable used in your Lab 3 assignment. And as such, Gets has the same functionality as in Lab 3 except that it strips off the newline character before storing the input string.
Consider the following exploit code, which runs the program into an infinite loop:

```c
infinite.o: file format elf32-i386
Disassembly of section .text:

00000000 <.text>:
0: 68 fc b2 ff bf push $0xbfffb2fc
5: c3 ret
6: 89 f6 mov %esi,%esi
```

Here is a disassembled version of the getbuf function in bufbomb, along with the values of the relevant registers and a printout of the stack before the call to Gets().

```
(gdb) disas
Dump of assembler code for function getbuf:
0x8048a44 <getbuf>: push %ebp
0x8048a45 <getbuf+1>: mov %esp,%ebp
0x8048a47 <getbuf+3>: sub $0x18,%esp
0x8048a4a <getbuf+6>: add $0xffffffff4,%esp
0x8048a4d <getbuf+9>: lea 0xffffffff4(%ebp),%eax
0x8048a50 <getbuf+12>: push %eax
0x8048a51 <getbuf+13>: call 0x8048b50 <Gets>
0x8048a56 <getbuf+18>: mov $0x1,%eax
0x8048a5b <getbuf+23>: mov %ebp,%esp
0x8048a5d <getbuf+25>: pop %ebp
0x8048a5e <getbuf+26>: ret
0x8048a5f <getbuf+27>: nop
End of assembler dump.
```

```
(gdb) info registers
eax 0xbfffb2fc ecx 0xffffffff
edx 0x0 ebx 0x0
esp 0xbfffb2e0 ebp 0xbfffb308
esi 0xffffffff edi 0x804b820
```

```
(gdb) x/20xb $ebp-12
0xbfffb2fc: 0xf0 0x17 0x02 0x40 0x18 0xb3 0xff 0xbf
0xbfffb304: 0x50 0x80 0x06 0x40 0x28 0xb3 0xff 0xbf
0xbfffb30c: 0xee 0x89 0x04 0x24 0xb3 0xff 0xbf
```

Page 7 of 11
Here are the questions:

1. Write down the address of the location on the stack which contains the return address where `getbuf` is supposed to return to:

   0x____________________

2. Using the exploit code illustrated above, fill in the the following blanks on the stack after the call to `gets()`. All the numbers must be in a **two character hexadecimal** representation of a byte. We’ve already filled in the terminating \0 (0x00) character for you.

   (gdb) x/20xb $ebp-12
   0xbfffb2fc: 0x___ 0x___ 0x___ 0x___ 0x___ 0x___ 0x___ 0x___ 0xbfffb304: 0x___ 0x___ 0x___ 0x___ 0x___ 0x___ 0x___ 0x___ 0xbfffb30c: 0x___ 0x___ 0x___ 0x___ 0xb0 0xb3 0xff 0xbf

3. During the infinite loop, what is the value of `%ebp`?

   0x_________________________
Problem 7. (10 points):
This problem tests your understanding of both control flow and multidimensional array layout. Consider the following assembly code for a procedure moo():

```
moo:
    pushl %ebp
    movl %esp, %ebp
    pushl %edi
    pushl %esi
    pushl %ebx
    movl $0, %ecx
    movl $arr1, %edi
    movl $arr2+8, %esi
    movl 8(%ebp), %eax
    leal 0(,%eax,4), %ebx
    .L5:
        leal (%ecx,%ecx,2), %eax
        sall $2, %eax
        movl %ebx, %edx
        addl (%eax,%esi), %edx
        movl %edx, (%eax,%edi)
        incl %ecx
        cmpl $10, %ecx
        jle .L5
    movl %ecx, %eax
    popl %ebx
    popl %esi
    popl %edi
    popl %ebp
    ret
```
Based on the assembly code, fill in the blanks below in moo’s C source code. (Note: you may only use symbolic variables from the source code in your expressions below-do not use register names.) **Hint:** First figure out what the loop variable (i) is in the assembly and what the value of M is.

```c
#define M _____
#define N _____

int arr1[M][N];

int arr2[M][N];

int moo(int x)
{
    int i;
    for(_________; i < M; _______ )
    {
        arr1[_____][_____] = arr2[_____][_____]+______________;
    }
    return ______;
}
```
Problem 8. (8 points):
Consider the following C declarations:

```c
typedef struct {
    char    ID[2];
    double  weight;
    double  *components;
    short   momentum;
} Projectile;
```

A. Using the templates below (allowing a maximum of 24 bytes), indicate the allocation of data for structs of type `Projectile`. Mark off and label the areas for each individual element (arrays may be labeled as a single element). **Cross hatch the parts that are allocated, but not used, and be sure to clearly indicate the end of the structure. Assume the Linux alignment rules discussed in class.**

```
Projectile:

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23
+------------------------------------------------------------------+
|                                                                       |
+------------------------------------------------------------------+
```

B. How would you define the `Modified` structure to minimize the number of bytes allocated for the structure using the same fields as the `Projectile` structure?

```c
typedef struct {
    char    ID[2];
    double  weight;
    short   momentum;
} Modified;
```

C. What is the value of `sizeof(Modified)`?
