

15-213

“The course that gives CMU its Zip!”

Machine-Level Programming IV: Data Sept. 20, 2006

Structured Data

- Arrays
- Structs
- Unions

Data/Control

- Buffer overflow

Basic Data Types

Integral

- Stored & operated on in general registers
- Signed vs. unsigned depends on instructions used

Intel	GAS	Bytes	C
byte	b	1	[unsigned] char
word	w	2	[unsigned] short
double word	l	4	[unsigned] int
quad word	q	8	[unsigned] long int (x86-64)

Floating Point

- Stored & operated on in floating point registers

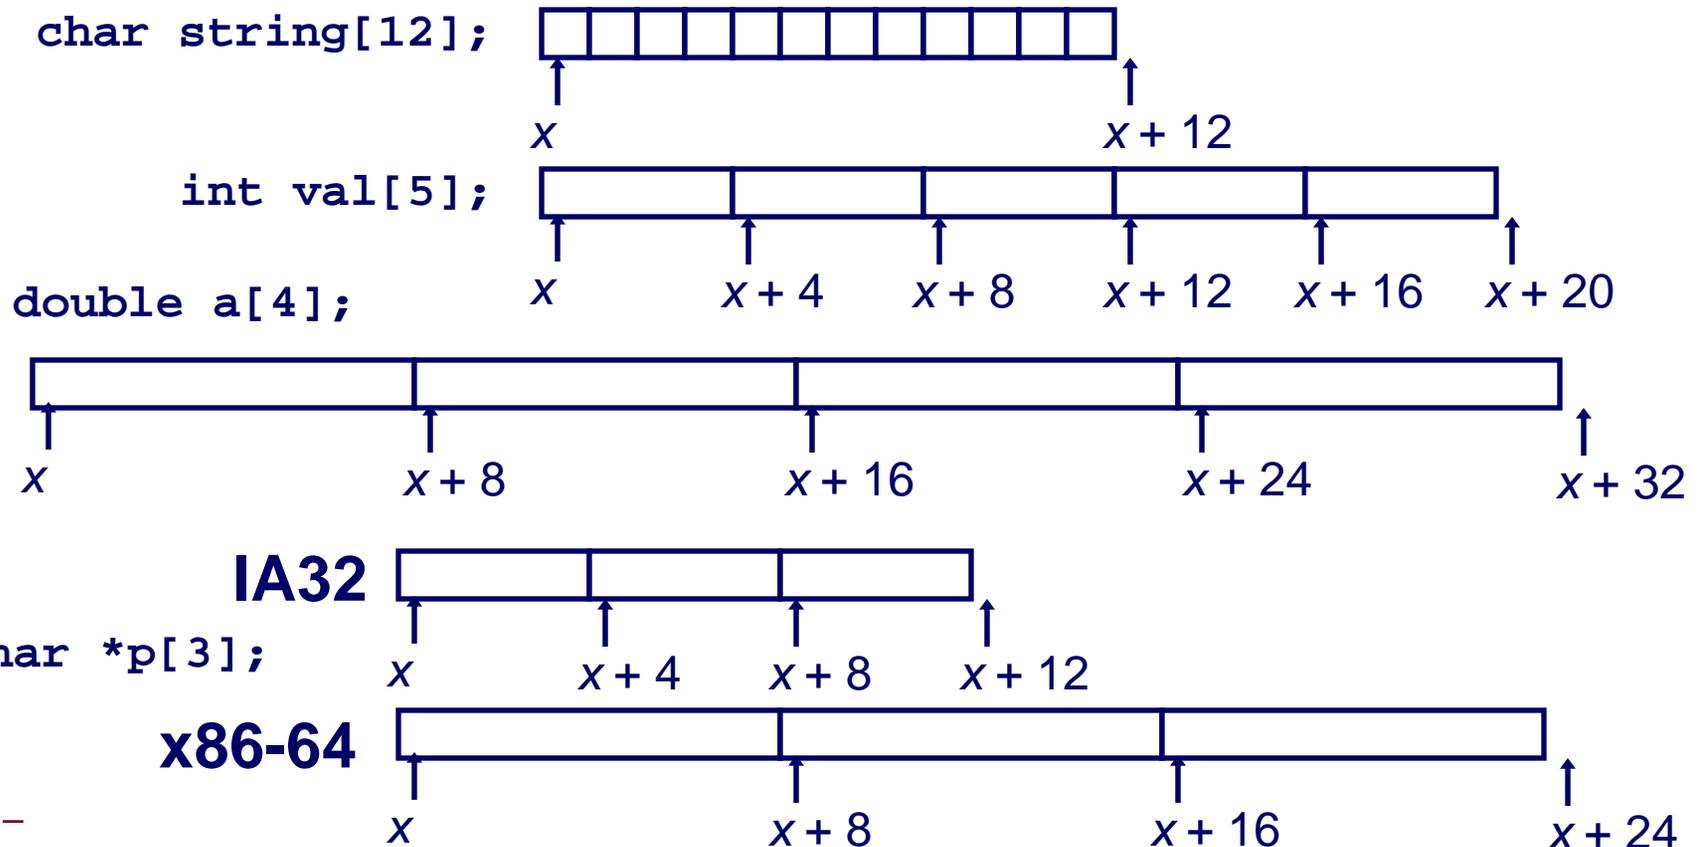

Intel	GAS	Bytes	C
Single	s	4	float
Double	l	8	double
Extended	t	10/12/16	long double

Array Allocation

Basic Principle

T $A[L];$

- Array of data type T and length L
- Contiguously allocated region of $L * \text{sizeof}(T)$ bytes

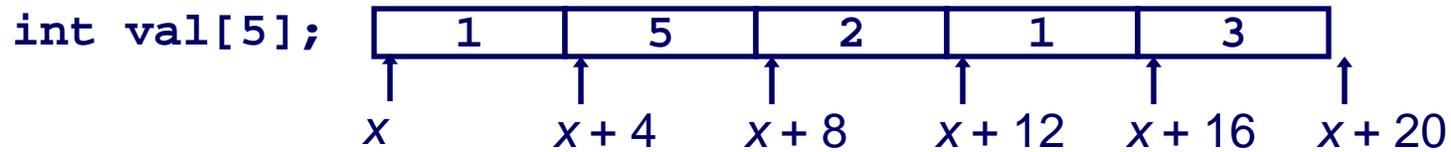

Array Access

Basic Principle

T $A[L]$;

- Array of data type T and length L
- Identifier A can be used as a pointer to array element 0
 - Type T^*

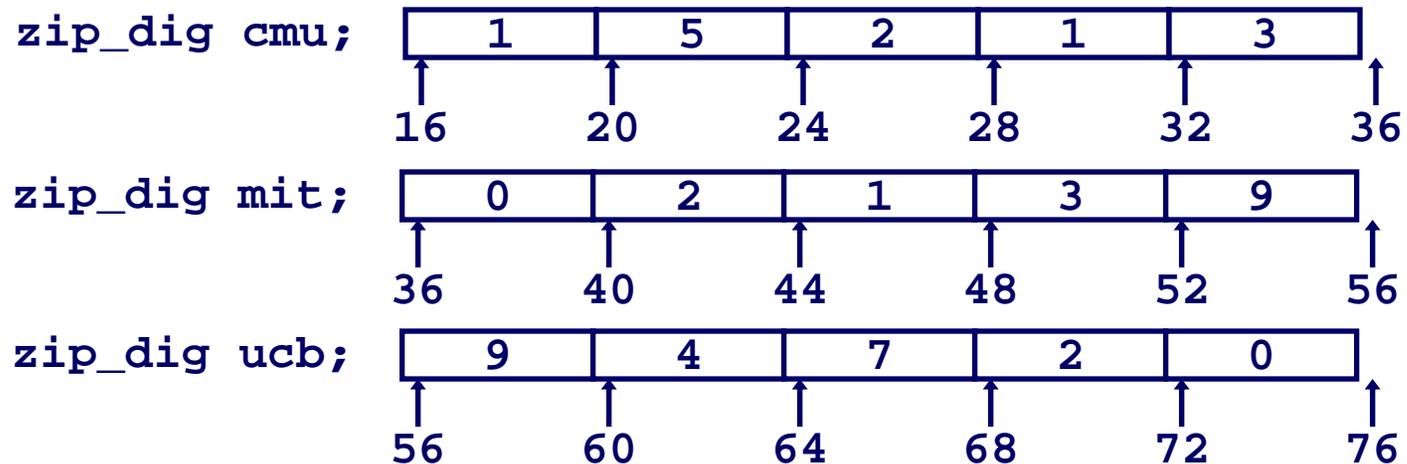

Reference Type Value

<code>val[4]</code>	<code>int</code>	3
<code>val</code>	<code>int *</code>	x
<code>val+1</code>	<code>int *</code>	$x+4$
<code>&val[2]</code>	<code>int *</code>	$x+8$
<code>val[5]</code>	<code>int</code>	??
<code>*(val+1)</code>	<code>int</code>	5
<code>val + i</code>	<code>int *</code>	$x+4i$

Array Example

```
typedef int zip_dig[5];  
  
zip_dig cmu = { 1, 5, 2, 1, 3 };  
zip_dig mit = { 0, 2, 1, 3, 9 };  
zip_dig ucb = { 9, 4, 7, 2, 0 };
```

Notes

- Declaration “zip_dig cmu” equivalent to “int cmu[5]”
- Example arrays were allocated in successive 20 byte blocks
 - Not guaranteed to happen in general

Array Accessing Example

Computation

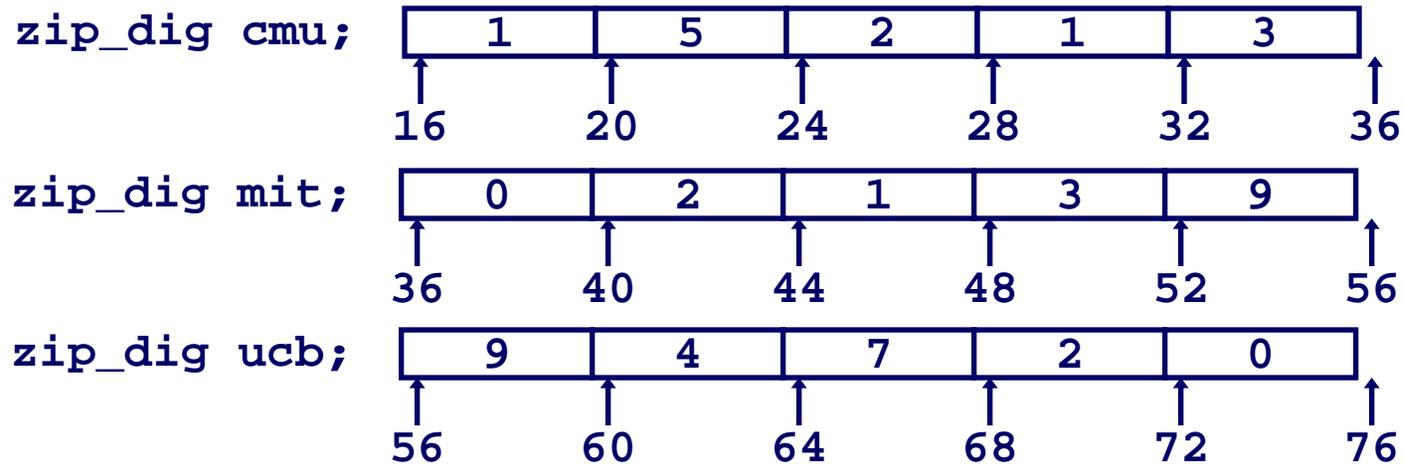

- Register `%edx` contains starting address of array
- Register `%eax` contains array index
- Desired digit at $4 * \%eax + \%edx$
- Use memory reference
(`%edx,%eax,4`)

```
int get_digit
(zip_dig z, int dig)
{
    return z[dig];
}
```

IA32 Memory Reference Code

```
# %edx = z
# %eax = dig
movl (%edx,%eax,4),%eax # z[dig]
```

Referencing Examples

Code Does Not Do Any Bounds Checking!

Reference	Address	Value	Guaranteed?
mit[3]	$36 + 4 * 3 = 48$	3	Yes
mit[5]	$36 + 4 * 5 = 56$	9	No
mit[-1]	$36 + 4 * -1 = 32$	3	No
cmu[15]	$16 + 4 * 15 = 76$??	No

■ Out of range behavior implementation-dependent

● No guaranteed relative allocation of different arrays

Array Loop Example

Original Source

```
int zd2int(zip_dig z)
{
    int i;
    int zi = 0;
    for (i = 0; i < 5; i++) {
        zi = 10 * zi + z[i];
    }
    return zi;
}
```

Transformed Version

- As generated by GCC
- Eliminate loop variable *i*
- Convert array code to pointer code
- Express in do-while form
 - No need to test at entrance

```
int zd2int(zip_dig z)
{
    int zi = 0;
    int *zend = z + 4;
    do {
        zi = 10 * zi + *z;
        z++;
    } while (z <= zend);
    return zi;
}
```

Array Loop Implementation (IA32)

Registers

```
%ecx z
%eax zi
%ebx zend
```

Computations

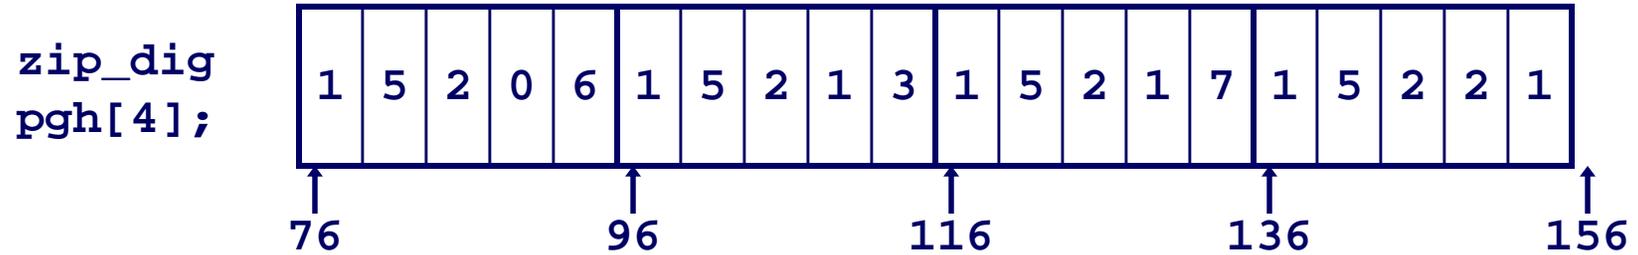

- $10 * z_i + *z$ implemented as
 $*z + 2 * (z_i + 4 * z_i)$
 $z++$ increments by 4

```
int zd2int(zip_dig z)
{
    int zi = 0;
    int *zend = z + 4;
    do {
        zi = 10 * zi + *z;
        z++;
    } while(z <= zend);
    return zi;
}
```

```
# %ecx = z
xorl %eax,%eax          # zi = 0
leal 16(%ecx),%ebx      # zend = z+4
.L59:
leal (%eax,%eax,4),%edx # 5*zi
movl (%ecx),%eax       # *z
addl $4,%ecx           # z++
leal (%eax,%edx,2),%eax # zi = *z + 2*(5*zi)
cmpl %ebx,%ecx       # z : zend
jle .L59             # if <= goto loop
```

Nested Array Example

```
#define PCOUNT 4
zip_dig pgh[PCOUNT] =
    {{1, 5, 2, 0, 6},
     {1, 5, 2, 1, 3},
     {1, 5, 2, 1, 7},
     {1, 5, 2, 2, 1}};
```

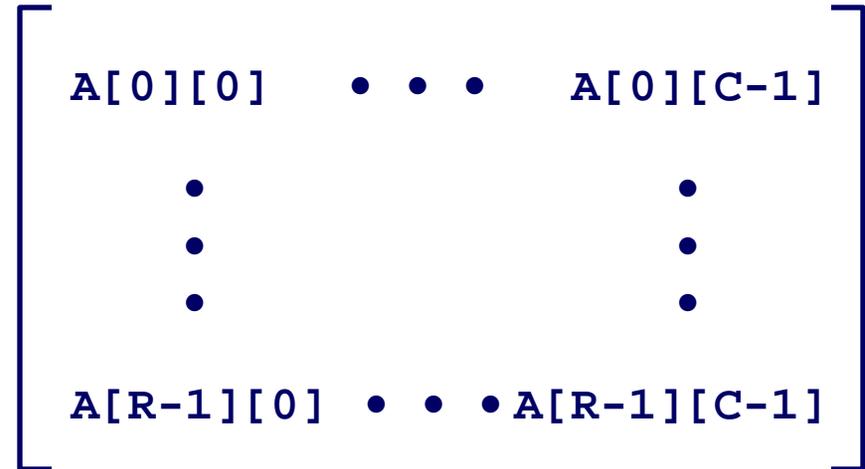

- Declaration “zip_dig pgh[4]” equivalent to “int pgh[4][5]”
 - Variable pgh denotes array of 4 elements
 - » Allocated contiguously
 - Each element is an array of 5 int’s
 - » Allocated contiguously
- “Row-Major” ordering of all elements guaranteed

Viewing as Multidimensional Array

Declaration

`T A[R][C];`

- 2D array of data type *T*
- *R* rows, *C* columns
- Type *T* element requires *K* bytes

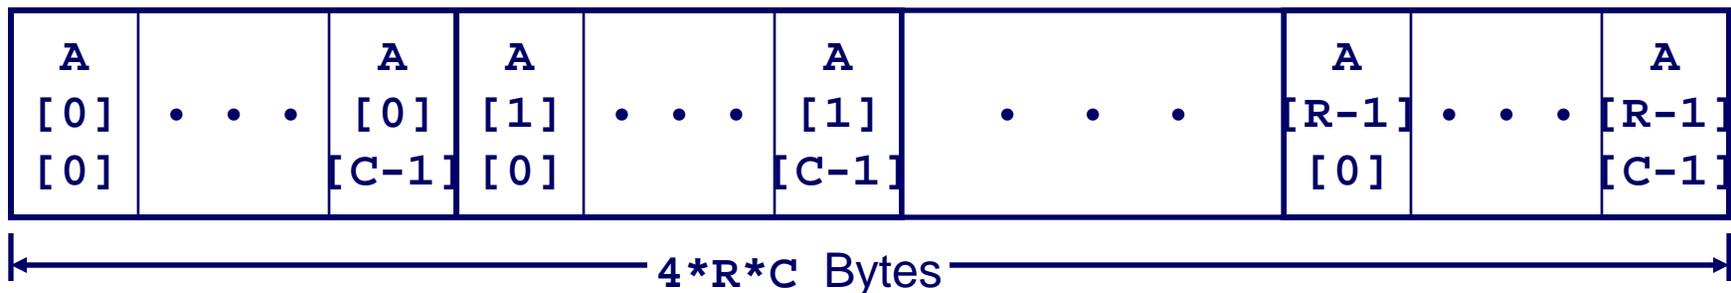

Array Size

- $R * C * K$ bytes

Arrangement

- Row-Major Ordering

`int A[R][C];`

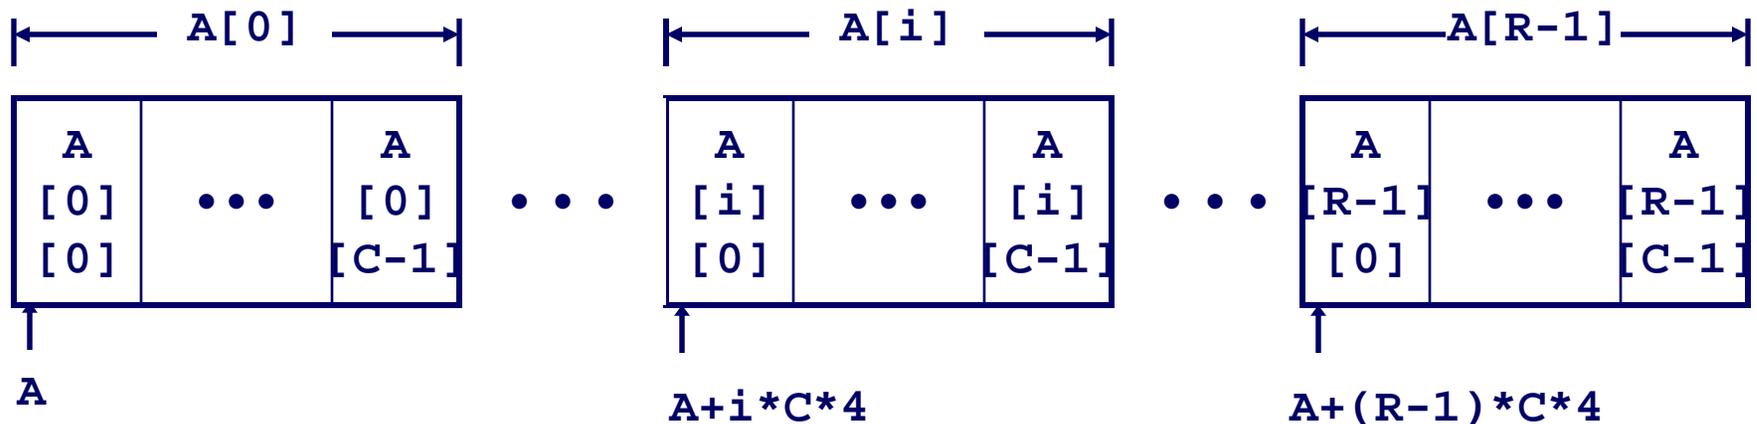

Nested Array Row Access

Row Vectors

- $A[i]$ is array of C elements
- Each element of type T
- Starting address $A + i * (C * K)$

```
int A[R][C];
```

Nested Array Row Access Code

```
int *get_pgh_zip(int index)
{
    return pgh[index];
}
```

Row Vector

- `pgh[index]` is array of 5 int's
- Starting address `pgh+20*index`

IA32 Code

- Computes and returns address
- Compute as `pgh + 4*(index+4*index)`

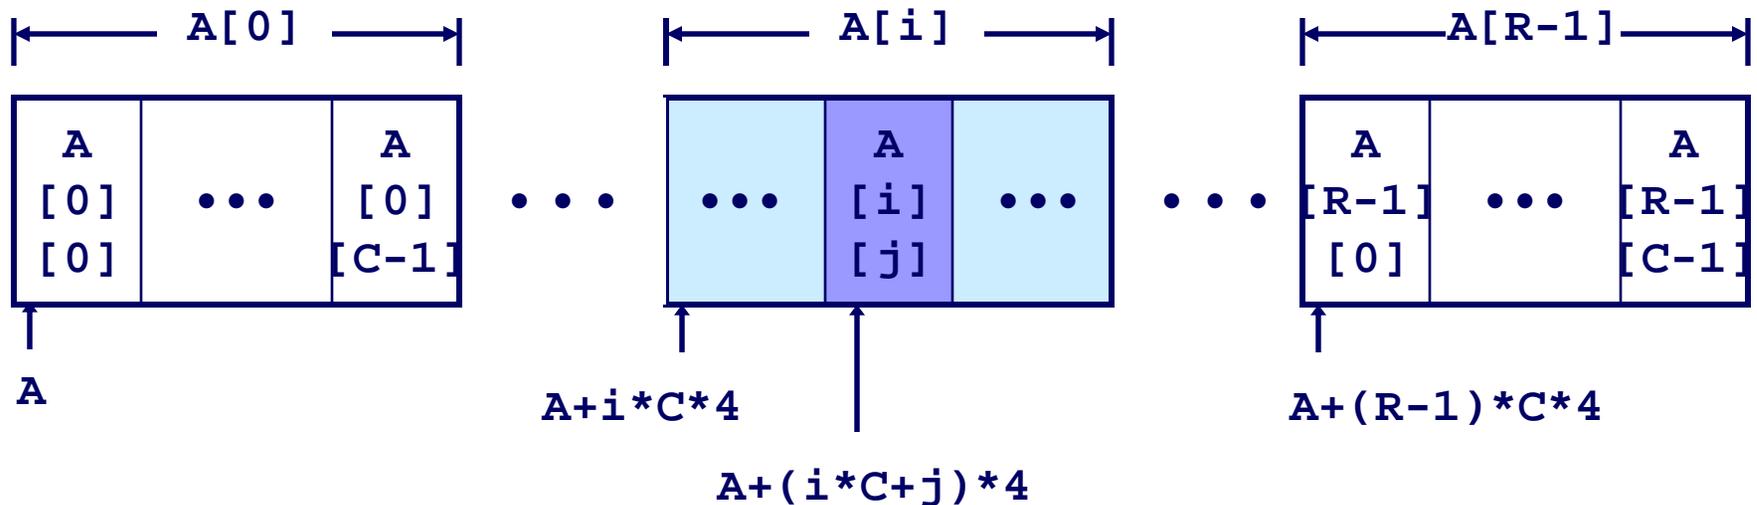

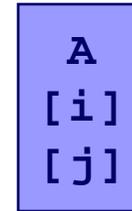

```
# %eax = index
leal (%eax,%eax,4),%eax # 5 * index
leal pgh(,%eax,4),%eax # pgh + (20 * index)
```

Nested Array Element Access

Array Elements

- $A[i][j]$ is element of type T
- Address $A + i * (C * K) + j * K$
 $= A + (i * C + j) * K$

`int A[R][C];`

Nested Array Element Access Code

Array Elements

- `pgh[index][dig]` is int
- Address:
 $pgh + 20 * index + 4 * dig$

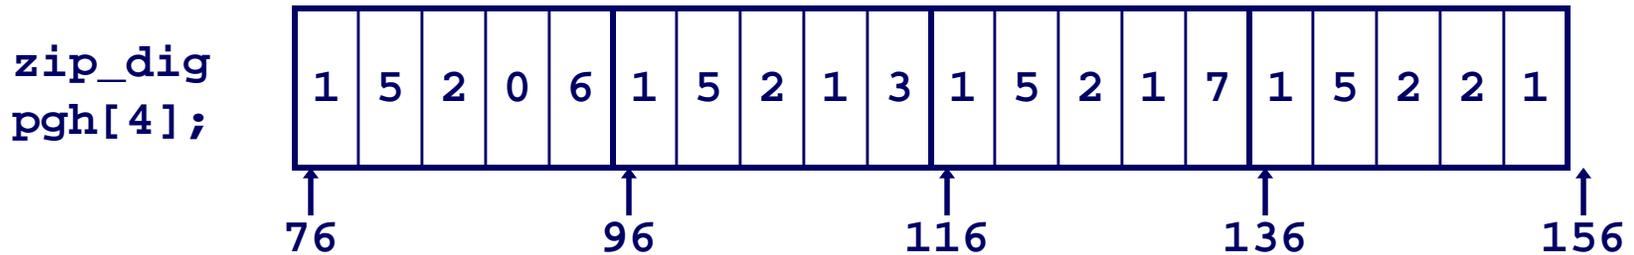

```
int get_pgh_digit
(int index, int dig)
{
    return pgh[index][dig];
}
```

IA32 Code

- Computes address
 $pgh + 4 * dig + 4 * (index + 4 * index)$
- `movl` performs memory reference

```
# %ecx = dig
# %eax = index
leal 0(,%ecx,4),%edx      # 4*dig
leal (%eax,%eax,4),%eax   # 5*index
movl pgh(%edx,%eax,4),%eax # *(pgh + 4*dig + 20*index)
```

Strange Referencing Examples

Reference	Address	Value	Guaranteed?
pgh[3][3]	$76+20*3+4*3 = 148$	2	Yes
pgh[2][5]	$76+20*2+4*5 = 136$	1	Yes
pgh[2][-1]	$76+20*2+4*-1 = 112$	3	Yes
pgh[4][-1]	$76+20*4+4*-1 = 152$	1	Yes
pgh[0][19]	$76+20*0+4*19 = 152$	1	Yes
pgh[0][-1]	$76+20*0+4*-1 = 72$??	No

- Code does not do any bounds checking
- Ordering of elements within array guaranteed

Multi-Level Array Example

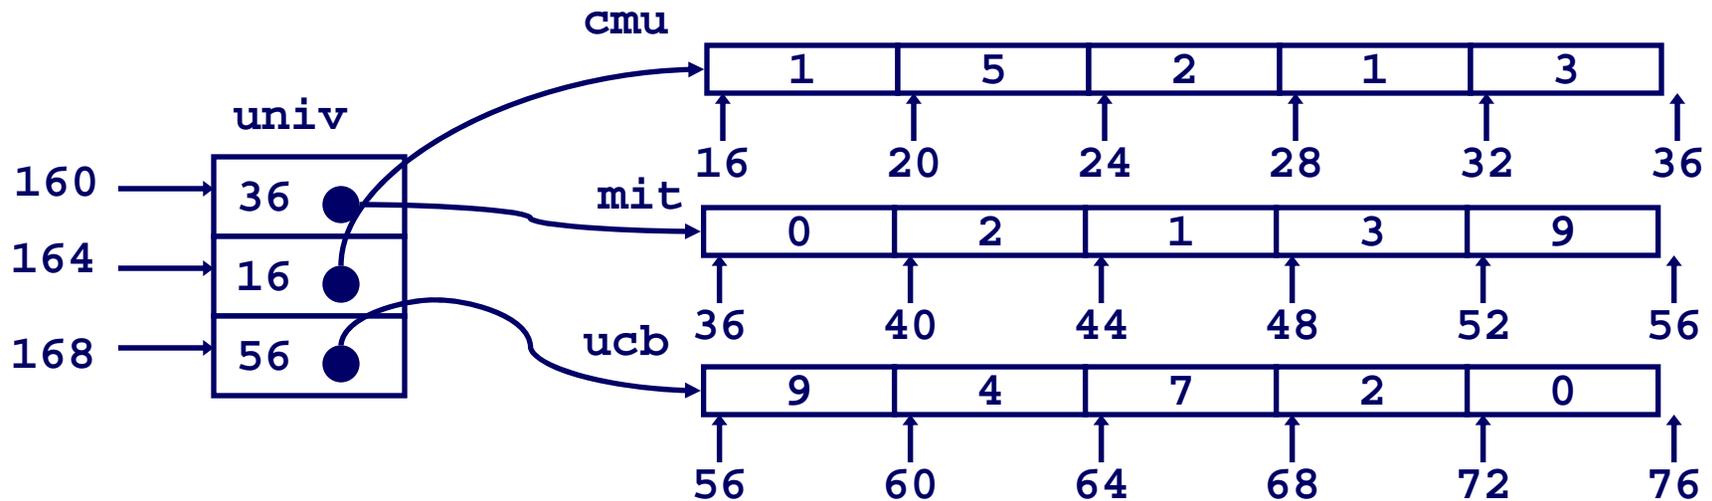

- Variable `univ` denotes array of 3 elements

- Each element is a pointer
 - 4 bytes

- Each pointer points to array of `int`'s

```
zip_dig cmu = { 1, 5, 2, 1, 3 };  
zip_dig mit = { 0, 2, 1, 3, 9 };  
zip_dig ucb = { 9, 4, 7, 2, 0 };
```

```
#define UCOUNT 3  
int *univ[UCOUNT] = {mit, cmu, ucb};
```

Element Access in Multi-Level Array

```
int get_univ_digit
(int index, int dig)
{
    return univ[index][dig];
}
```

Computation (IA32)

- Element access
Mem[Mem[univ+4*index]+4*dig]
- Must do two memory reads
 - First get pointer to row array
 - Then access element within array

```
# %ecx = index
# %eax = dig
leal 0(,%ecx,4),%edx      # 4*index
movl univ(%edx),%edx      # Mem[univ+4*index]
movl (%edx,%eax,4),%eax   # Mem[...+4*dig]
```

Array Element Accesses

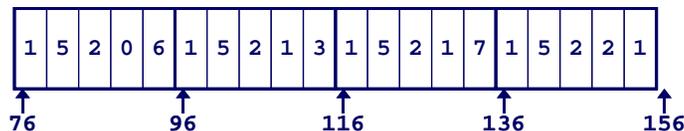

- Similar C references

Nested Array

```
int get_pgh_digit
(int index, int dig)
{
    return pgh[index][dig];
}
```

- Element at

$\text{Mem}[\text{pgh} + 20 * \text{index} + 4 * \text{dig}]$

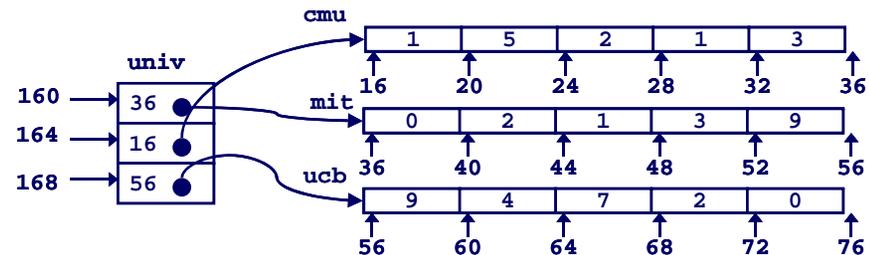

- Different address computation

Multi-Level Array

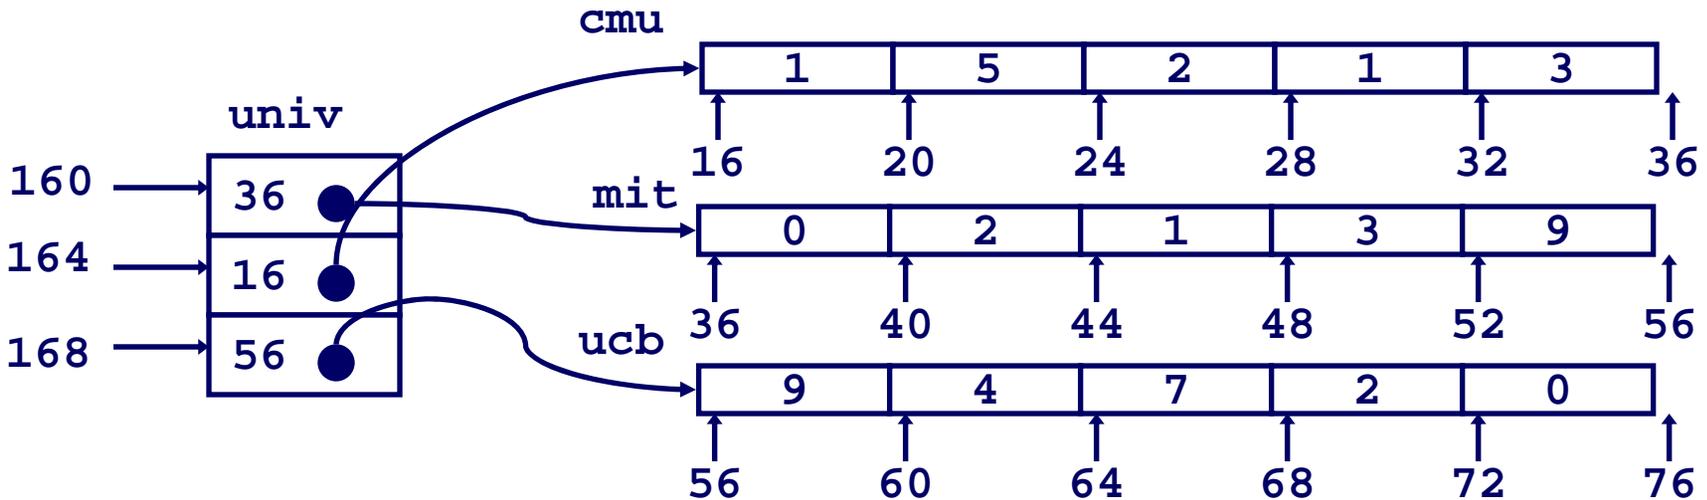

```
int get_univ_digit
(int index, int dig)
{
    return univ[index][dig];
}
```

- Element at

$\text{Mem}[\text{Mem}[\text{univ} + 4 * \text{index}] + 4 * \text{dig}]$

Strange Referencing Examples

Reference	Address	Value	Guaranteed?
<code>univ[2][3]</code>	$56 + 4 * 3 = 68$	2	Yes
<code>univ[1][5]</code>	$16 + 4 * 5 = 36$	0	No
<code>univ[2][-1]</code>	$56 + 4 * -1 = 52$	9	No
<code>univ[3][-1]</code>	??	??	No
<code>univ[1][12]</code>	$16 + 4 * 12 = 64$	7	No

- Code does not do any bounds checking
- Ordering of elements in different arrays not guaranteed

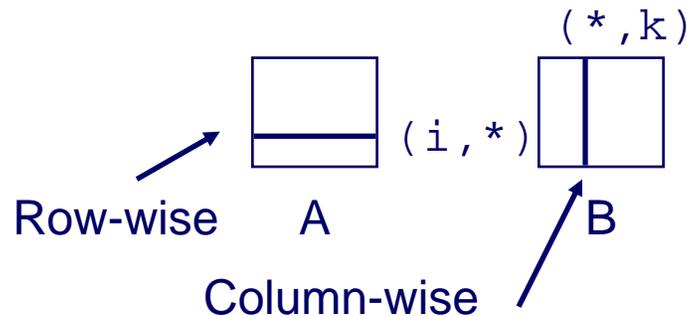

Using Nested Arrays

Strengths

- C compiler handles doubly subscripted arrays
- Generates very efficient code
 - Avoids multiply in index computation

Limitation

- Only works if have fixed array size

```
#define N 16
typedef int fix_matrix[N][N];
```

```
/* Compute element i,k of
   fixed matrix product */
int fix_prod_ele
(fix_matrix a, fix_matrix b,
 int i, int k)
{
    int j;
    int result = 0;
    for (j = 0; j < N; j++)
        result += a[i][j]*b[j][k];
    return result;
}
```

Dynamic Nested Arrays

Strength

- Can create matrix of arbitrary size

Programming

- Must do index computation explicitly

Performance

- Accessing single element costly
- Must do multiplication

```
int * new_var_matrix(int n)
{
    return (int *)
        calloc(sizeof(int), n*n);
}
```

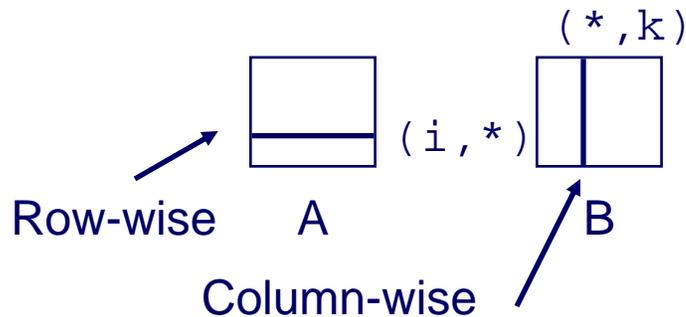

```
int var_ele
(int *a, int i,
 int j, int n)
{
    return a[i*n+j];
}
```

```
movl 12(%ebp),%eax    # i
movl 8(%ebp),%edx    # a
imull 20(%ebp),%eax  # n*i
addl 16(%ebp),%eax   # n*i+j
movl (%edx,%eax,4),%eax # Mem[a+4*(i*n+j)]
```

Dynamic Array Multiplication

Without Optimizations

- **Multiplies**
 - 2 for subscripts
 - 1 for data
- **Adds**
 - 4 for array indexing
 - 1 for loop index
 - 1 for data

```
/* Compute element i,k of
   variable matrix product */
int var_prod_ele
(int *a, int *b,
 int i, int k, int n)
{
  int j;
  int result = 0;
  for (j = 0; j < n; j++)
    result +=
      a[i*n+j] * b[j*n+k];
  return result;
}
```

Optimizing Dynamic Array Mult.

Optimizations

- Performed when set optimization level to `-O2`

Code Motion

- Expression `i*n` can be computed outside loop

Strength Reduction

- Incrementing `j` has effect of incrementing `j*n+k` by `n`

Performance

- Compiler can optimize regular access patterns

```
{  
    int j;  
    int result = 0;  
    for (j = 0; j < n; j++)  
        result +=  
            a[i*n+j] * b[j*n+k];  
    return result;  
}
```

```
{  
    int j;  
    int result = 0;  
    int iTn = i*n;  
    int jTnPk = k;  
    for (j = 0; j < n; j++) {  
        result +=  
            a[iTn+j] * b[jTnPk];  
        jTnPk += n;  
    }  
    return result;  
}
```

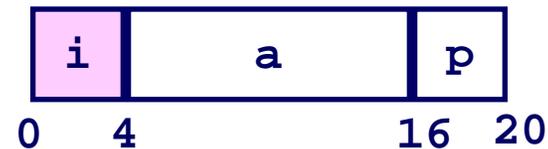

Structures

Concept

- Contiguously-allocated region of memory
- Refer to members within structure by names
- Members may be of different types

```
struct rec {  
    int i;  
    int a[3];  
    int *p;  
};
```

Memory Layout

Accessing Structure Member

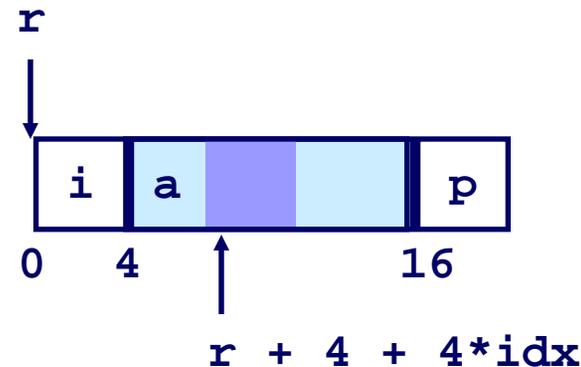

```
void  
set_i(struct rec *r,  
      int val)  
{  
    r->i = val;  
}
```

IA32 Assembly

```
# %eax = val  
# %edx = r  
movl %eax, (%edx)    # Mem[r] = val
```

Generating Pointer to Struct. Member

```
struct rec {  
    int i;  
    int a[3];  
    int *p;  
};
```

Generating Pointer to Array Element

- Offset of each structure member determined at compile time

```
int *  
find_a  
(struct rec *r, int idx)  
{  
    return &r->a[idx];  
}
```

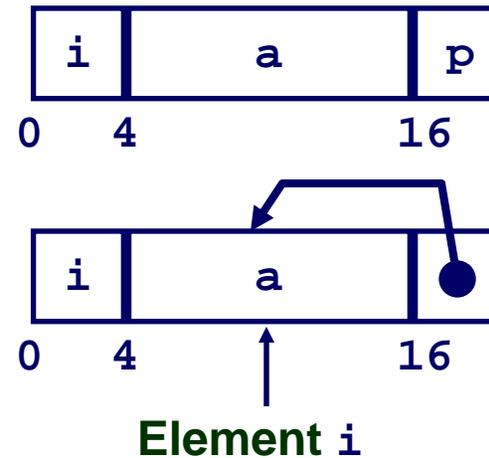

```
# %ecx = idx  
# %edx = r  
leal 0(,%ecx,4),%eax    # 4*idx  
leal 4(%eax,%edx),%eax  # r+4*idx+4
```

Structure Referencing (Cont.)

C Code

```
struct rec {  
    int i;  
    int a[3];  
    int *p;  
};
```

```
void  
set_p(struct rec *r)  
{  
    r->p =  
        &r->a[r->i];  
}
```

```
# %edx = r  
movl (%edx),%ecx          # r->i  
leal 0(,%ecx,4),%eax      # 4*(r->i)  
leal 4(%edx,%eax),%eax    # r+4+4*(r->i)  
movl %eax,16(%edx)       # Update r->p
```

Alignment

Aligned Data

- Primitive data type requires K bytes
- Address must be multiple of K
- Required on some machines; advised on IA32
 - treated differently by IA32 Linux, x86-64 Linux, and Windows!

Motivation for Aligning Data

- Memory accessed by (aligned) chunks of 4 or 8 bytes (system dependent)
 - Inefficient to load or store datum that spans quad word boundaries
 - Virtual memory very tricky when datum spans 2 pages

Compiler

- Inserts gaps in structure to ensure correct alignment of fields

Specific Cases of Alignment (IA32)

Size of Primitive Data Type:

- 1 byte (e.g., char)
 - no restrictions on address
- 2 bytes (e.g., short)
 - lowest 1 bit of address must be 0_2
- 4 bytes (e.g., int, float, char *, etc.)
 - lowest 2 bits of address must be 00_2
- 8 bytes (e.g., double)
 - Windows (and most other OS's & instruction sets):
 - » lowest 3 bits of address must be 000_2
 - Linux:
 - » lowest 2 bits of address must be 00_2
 - » i.e., treated the same as a 4-byte primitive data type
- 12 bytes (long double)
 - Windows, Linux:
 - » lowest 2 bits of address must be 00_2
 - » i.e., treated the same as a 4-byte primitive data type

Specific Cases of Alignment (x86-64)

Size of Primitive Data Type:

- 1 byte (e.g., char)
 - no restrictions on address
- 2 bytes (e.g., short)
 - lowest 1 bit of address must be 0_2
- 4 bytes (e.g., int, float)
 - lowest 2 bits of address must be 00_2
- 8 bytes (e.g., double, char *)
 - Windows & Linux:
 - » lowest 3 bits of address must be 000_2
- 16 bytes (long double)
 - Linux:
 - » lowest 3 bits of address must be 000_2
 - » i.e., treated the same as a 8-byte primitive data type

Satisfying Alignment with Structures

Offsets Within Structure

- Must satisfy element's alignment requirement

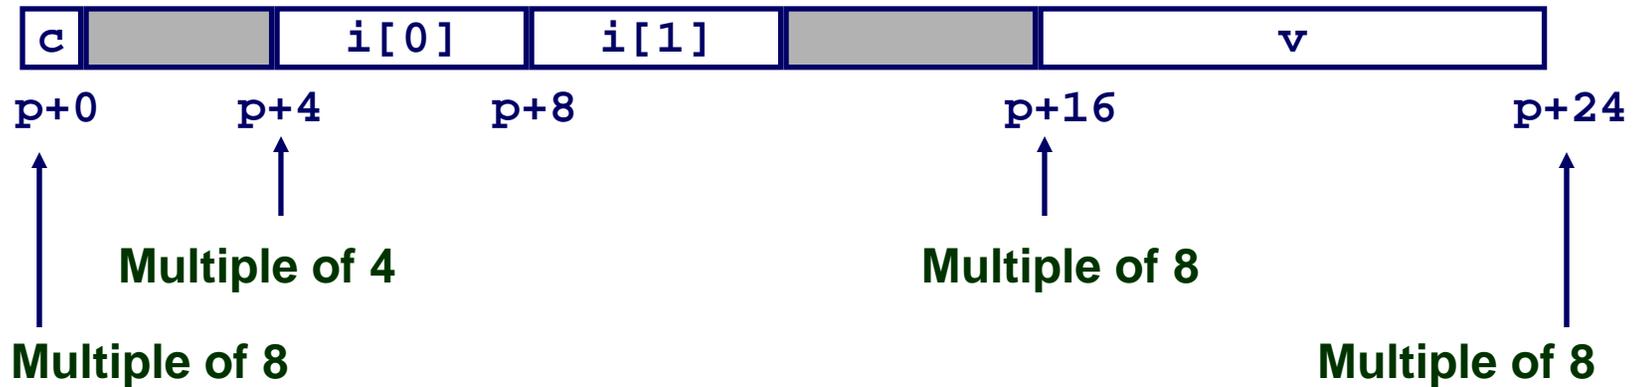

Overall Structure Placement

- Each structure has alignment requirement K
 - Largest alignment of any element
- Initial address & structure length must be multiples of K

```
struct s1 {  
    char c;  
    int i[2];  
    double v;  
} *p;
```

Example (under Windows or x86-64):

- $K = 8$, due to double element

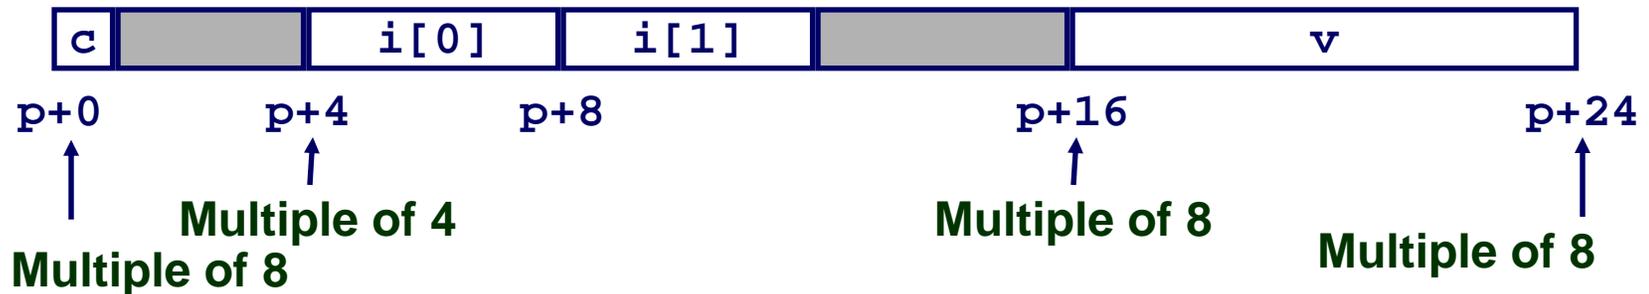

Different Alignment Conventions

```
struct s1 {  
    char c;  
    int i[2];  
    double v;  
} *p;
```

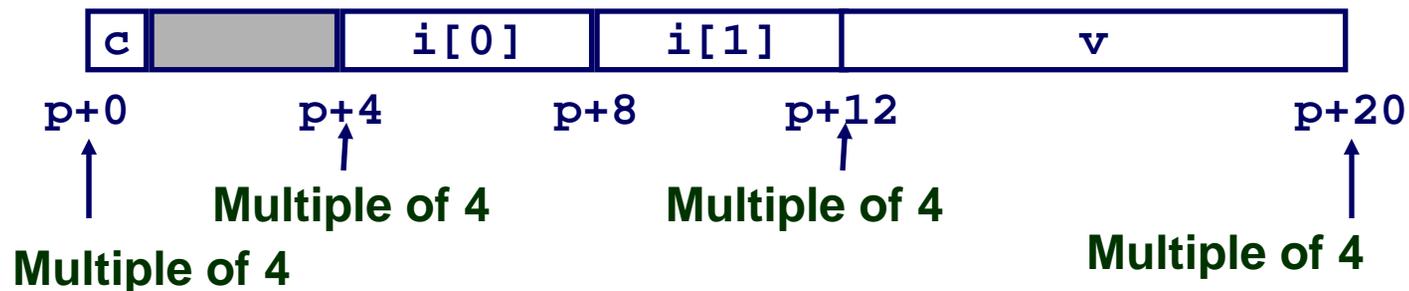

x86-64 or IA32 Windows:

- `K = 8`, due to `double` element

IA32 Linux

- `K = 4`; `double` treated like a 4-byte data type

Overall Alignment Requirement

```
struct s2 {  
    double x;  
    int i[2];  
    char c;  
} *p;
```

p must be multiple of:
8 for x86-64 or IA32 Windows
4 for IA32 Linux

p+0

p+8

p+12

p+16

Windows: p+24

Linux: p+20

```
struct s3 {  
    float x[2];  
    int i[2];  
    char c;  
} *p;
```

p must be multiple of 4 (all cases)

p+0

p+4

p+8

p+12

p+16

p+20

Ordering Elements Within Structure

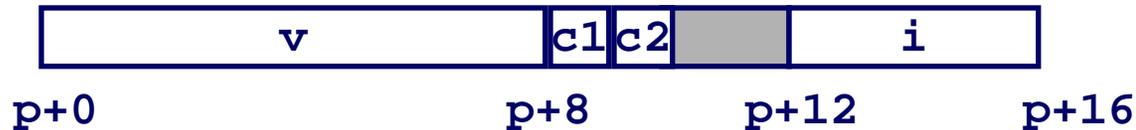

```
struct S4 {  
    char c1;  
    double v;  
    char c2;  
    int i;  
} *p;
```

10 bytes wasted space in Windows
or x86-64

```
struct S5 {  
    double v;  
    char c1;  
    char c2;  
    int i;  
} *p;
```

2 bytes wasted space

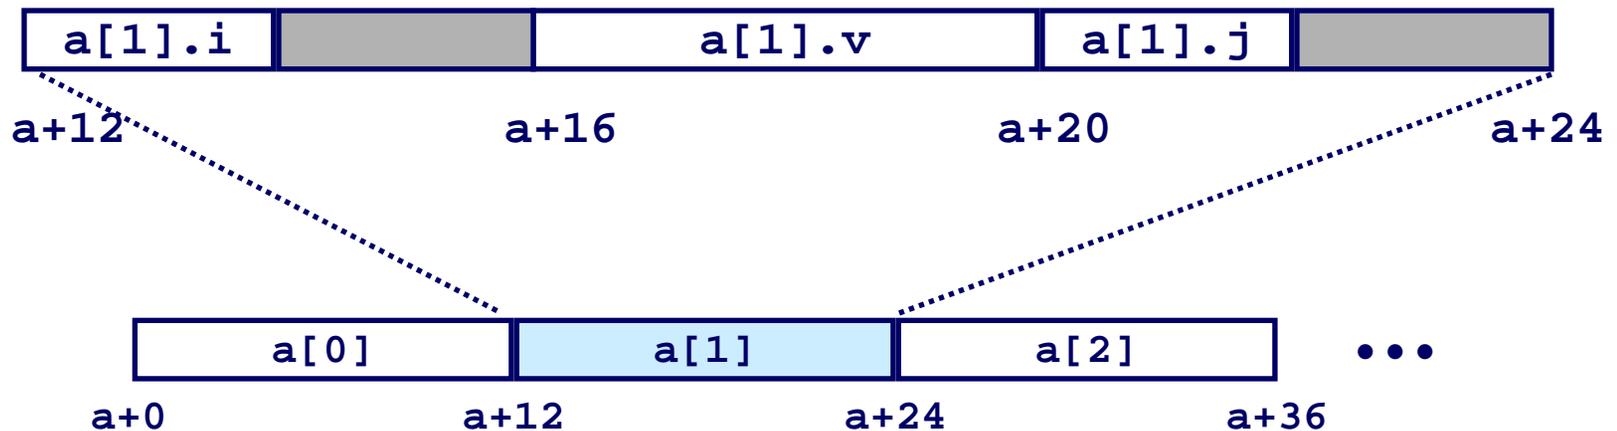

Arrays of Structures

Principle

- Allocated by repeating allocation for array type
- In general, may nest arrays & structures to arbitrary depth

```
struct s6 {  
    short i;  
    float v;  
    short j;  
} a[10];
```

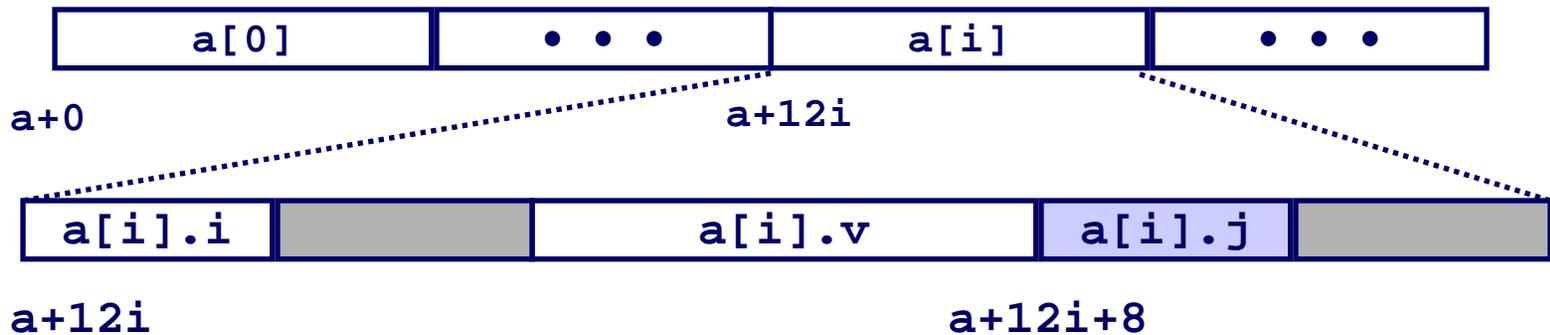

Accessing Element within Array

- Compute offset to start of structure
 - Compute $12*i$ as $4*(i+2i)$
- Access element according to its offset within structure
 - Offset by 8
 - Assembler gives displacement as $a + 8$
 - » Linker must set actual value

```
struct s6 {  
    short i;  
    float v;  
    short j;  
} a[10];
```

```
short get_j(int idx)  
{  
    return a[idx].j;  
}
```

```
# %eax = idx  
leal (%eax,%eax,2),%eax # 3*idx  
movswl a+8(,%eax,4),%eax
```

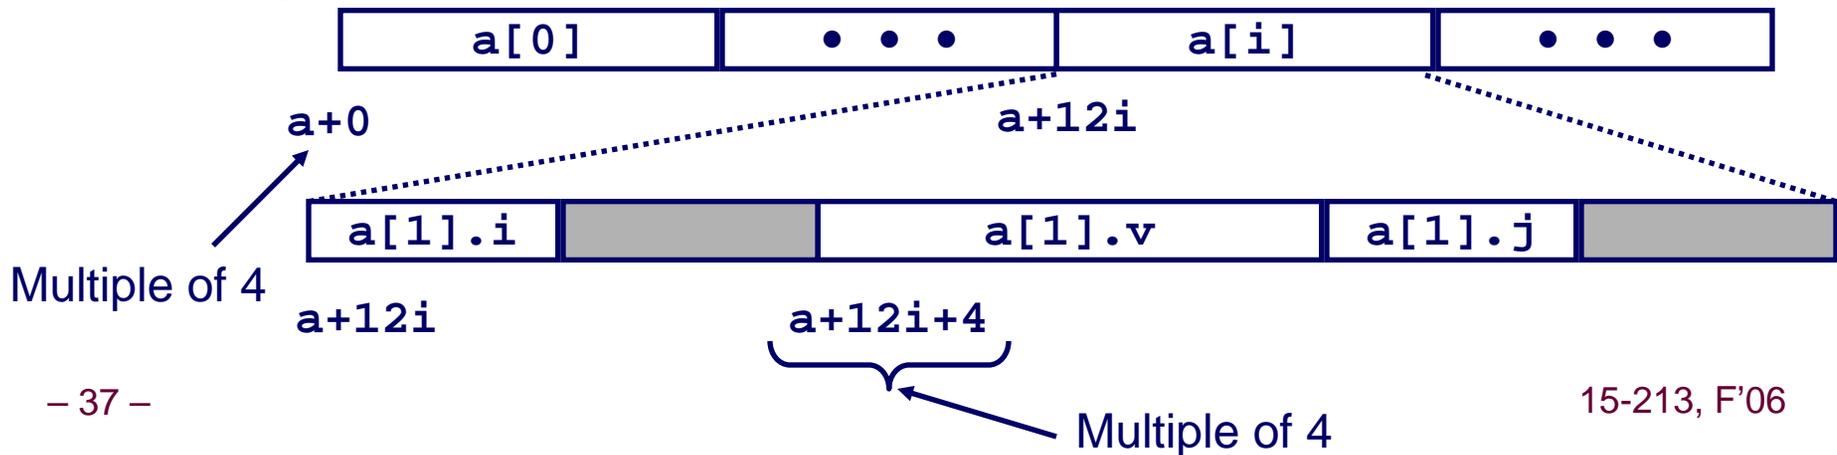

Satisfying Alignment within Structure

Achieving Alignment

- Starting address of structure array must be multiple of worst-case alignment for any element
 - a must be multiple of 4
- Offset of element within structure must be multiple of element's alignment requirement
 - v 's offset of 4 is a multiple of 4
- Overall size of structure must be multiple of worst-case alignment for any element
 - Structure padded with unused space to be 12 bytes

```
struct s6 {  
    short i;  
    float v;  
    short j;  
} a[10];
```

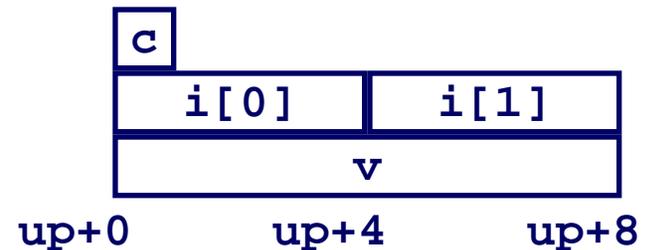

Union Allocation

Principles

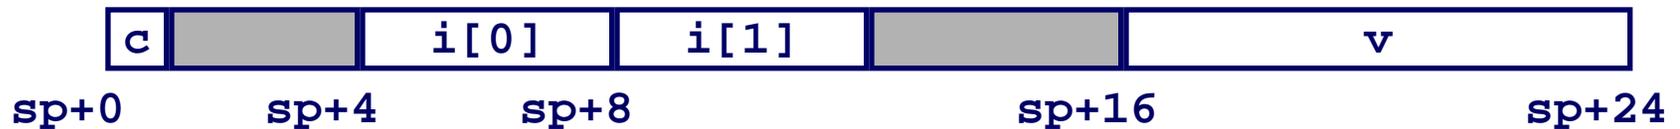

- Overlay union elements
- Allocate according to largest element
- Can only use one field at a time

```
struct s1 {  
    char c;  
    int i[2];  
    double v;  
} *sp;
```

```
union U1 {  
    char c;  
    int i[2];  
    double v;  
} *up;
```

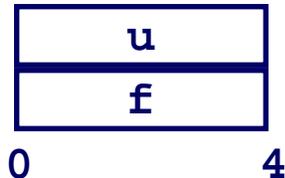

(Windows alignment)

Using Union to Access Bit Patterns

```
typedef union {  
    float f;  
    unsigned u;  
} bit_float_t;
```

- Get direct access to bit representation of float
- `bit2float` generates float with given bit pattern
 - NOT the same as `(float) u`
- `float2bit` generates bit pattern from float
 - NOT the same as `(unsigned) f`

```
float bit2float(unsigned u)  
{  
    bit_float_t arg;  
    arg.u = u;  
    return arg.f;  
}
```

```
unsigned float2bit(float f)  
{  
    bit_float_t arg;  
    arg.f = f;  
    return arg.u;  
}
```

Byte Ordering Revisited

Idea

- Short/long/quad words stored in memory as 2/4/8 consecutive bytes
- Which is most (least) significant?
- Can cause problems when exchanging binary data between machines

Big Endian

- Most significant byte has lowest address
- PowerPC, Sparc

Little Endian

- Least significant byte has lowest address
- Intel x86

Byte Ordering Example

```
union {  
    unsigned char c[8];  
    unsigned short s[4];  
    unsigned int i[2];  
    unsigned long l[1];  
} dw;
```

c[0]	c[1]	c[2]	c[3]	c[4]	c[5]	c[6]	c[7]
s[0]		s[1]		s[2]		s[3]	
i[0]				i[1]			
l[0]							

Byte Ordering Example (Cont).

```
int j;
for (j = 0; j < 8; j++)
    dw.c[j] = 0xf0 + j;

printf("Characters 0-7 ==
[0x%x,0x%x,0x%x,0x%x,0x%x,0x%x,0x%x,0x%x]\n",
    dw.c[0], dw.c[1], dw.c[2], dw.c[3],
    dw.c[4], dw.c[5], dw.c[6], dw.c[7]);

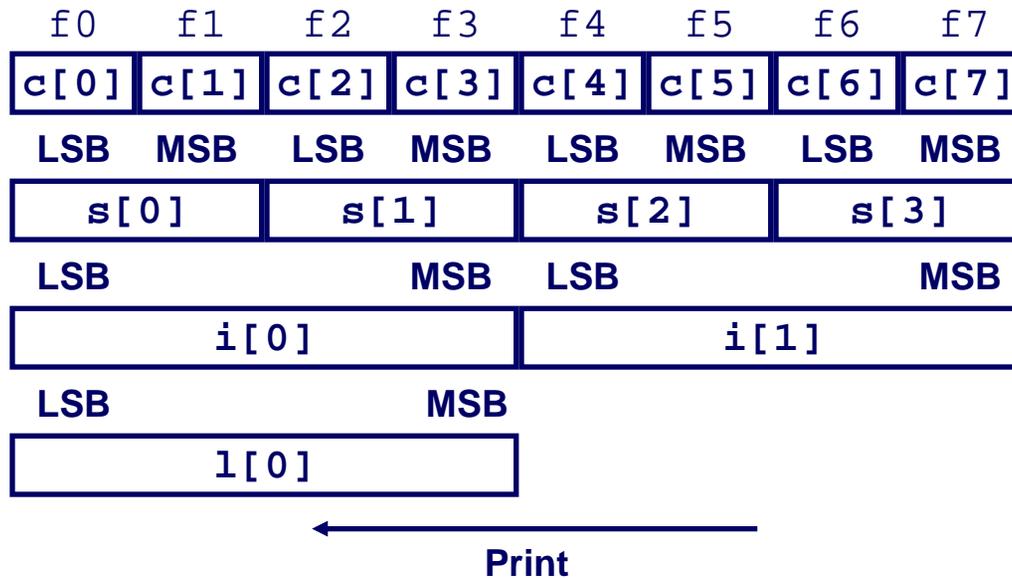

printf("Shorts 0-3 ==
[0x%x,0x%x,0x%x,0x%x]\n",
    dw.s[0], dw.s[1], dw.s[2], dw.s[3]);

printf("Ints 0-1 == [0x%x,0x%x]\n",
    dw.i[0], dw.i[1]);

printf("Long 0 == [0x%lx]\n",
    dw.l[0]);
```

Byte Ordering on IA32

Little Endian

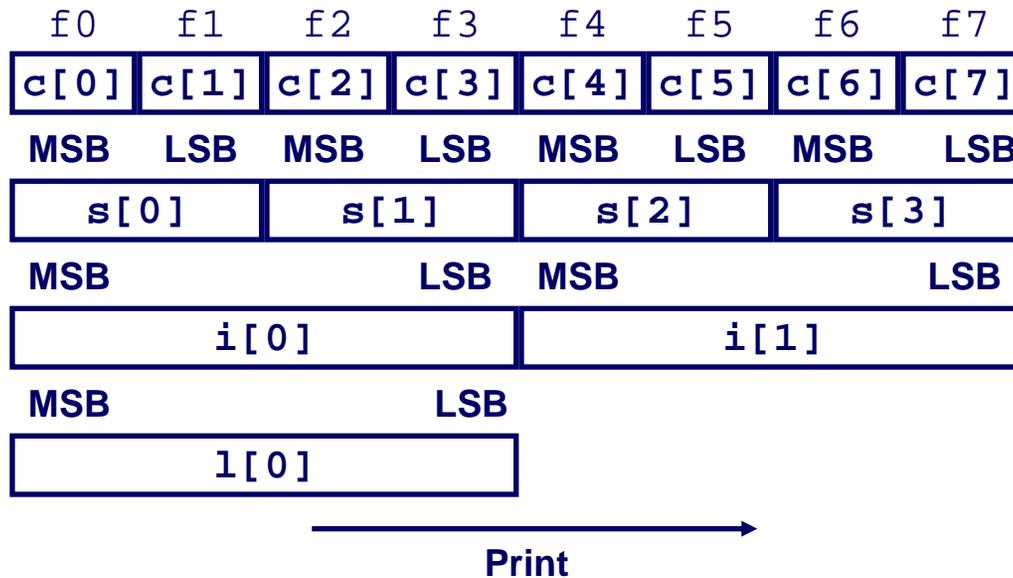

Output on IA32:

Characters 0-7 == [0xf0,0xf1,0xf2,0xf3,0xf4,0xf5,0xf6,0xf7]
Shorts 0-3 == [0xf1f0,0xf3f2,0xf5f4,0xf7f6]
Ints 0-1 == [0xf3f2f1f0,0xf7f6f5f4]
Long 0 == [0xf3f2f1f0]

Byte Ordering on Sun

Big Endian

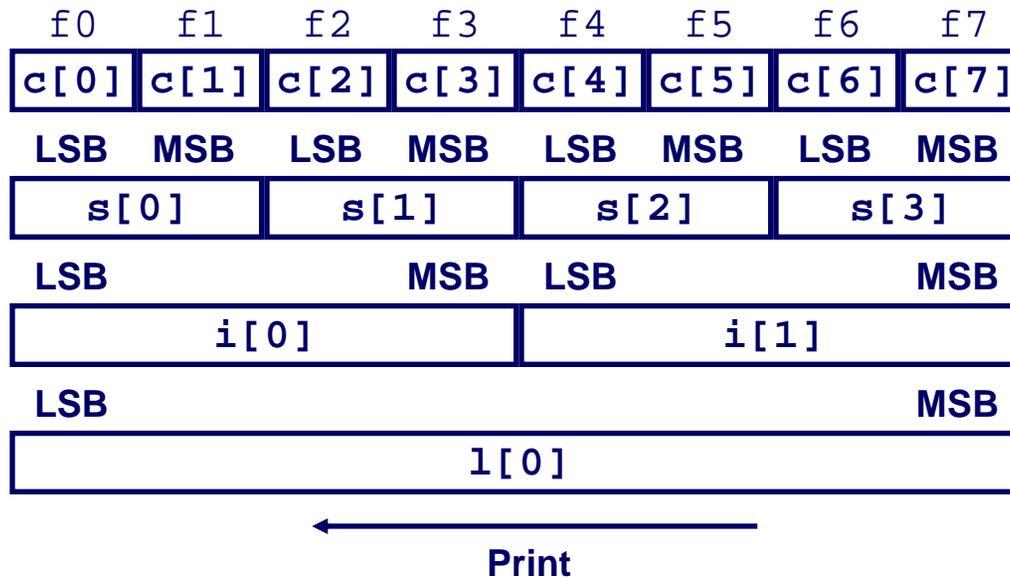

Output on Sun:

```
Characters 0-7 == [0xf0,0xf1,0xf2,0xf3,0xf4,0xf5,0xf6,0xf7]
Shorts     0-3 == [0xf0f1,0xf2f3,0xf4f5,0xf6f7]
Ints       0-1 == [0xf0f1f2f3,0xf4f5f6f7]
Long       0    == [0xf0f1f2f3]
```

Byte Ordering on x86-64

Little Endian

Output on x86-64:

Characters 0-7 == [0xf0,0xf1,0xf2,0xf3,0xf4,0xf5,0xf6,0xf7]
Shorts 0-3 == [0xf1f0,0xf3f2,0xf5f4,0xf7f6]
Ints 0-1 == [0xf3f2f1f0,0xf7f6f5f4]
Long 0 == [0xf7f6f5f4f3f2f1f0]

Buffer Overflow Attacks

November, 1988

- First Internet Worm spread over then-new Internet
- Many university machines compromised
- No malicious effect

Today

- Buffer overflow is still the initial entry for over 50% of network-based attacks

String Library Code

- Implementation of Unix function `gets()`
 - No way to specify limit on number of characters to read

```
/* Get string from stdin */
char *gets(char *dest)
{
    int c = getc();
    char *p = dest;
    while (c != EOF && c != '\n') {
        *p++ = c;
        c = getc();
    }
    *p = '\0';
    return dest;
}
```

- Similar problems with other Unix functions
 - `strcpy`: Copies string of arbitrary length
 - `scanf`, `fscanf`, `sscanf`, when given `%s` conversion specification

Vulnerable Buffer Code

```
/* Echo Line */  
void echo()  
{  
    char buf[4]; /* Way too small! */  
    gets(buf);  
    puts(buf);  
}
```

```
int main()  
{  
    printf("Type a string:");  
    echo();  
    return 0;  
}
```

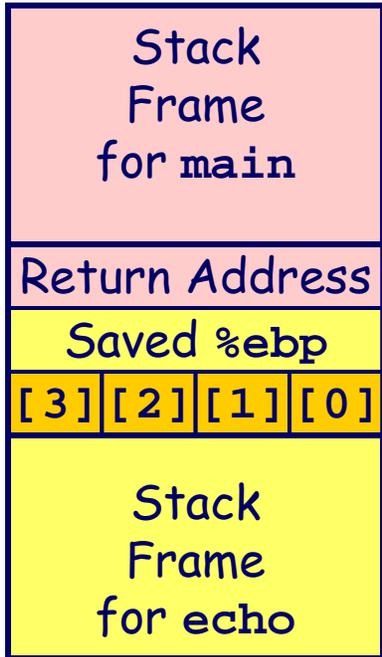

Buffer Overflow Executions

```
unix>./bufdemo  
Type a string:123  
123
```

```
unix>./bufdemo  
Type a string:12345  
Segmentation Fault
```

```
unix>./bufdemo  
Type a string:12345678  
Segmentation Fault
```

Buffer Overflow Stack (IA32)

```

/* Echo Line */
void echo()
{
    char buf[4]; /* Way too small! */
    gets(buf);
    puts(buf);
}

```

```

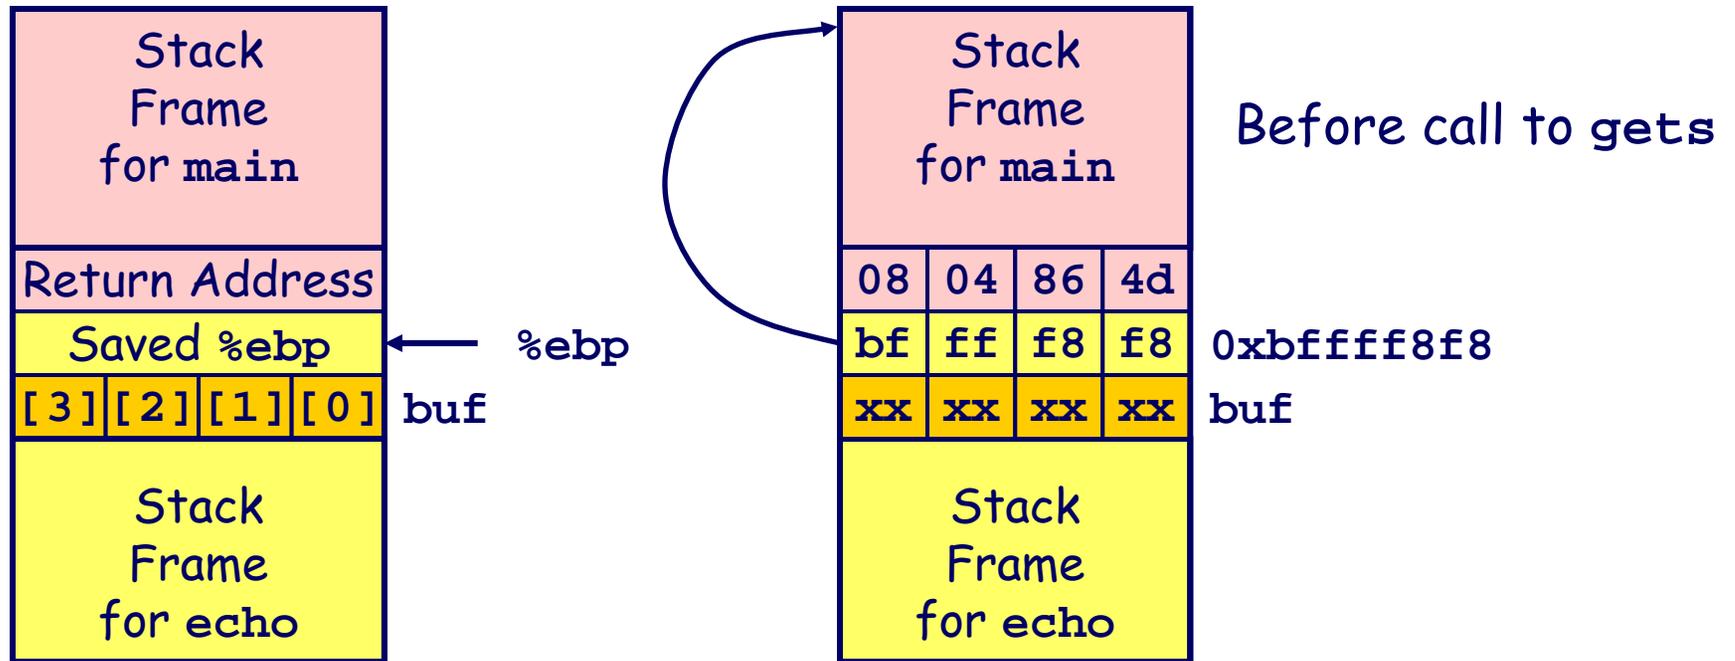

echo:
    pushl %ebp           # Save %ebp on stack
    movl %esp,%ebp
    subl $20,%esp       # Allocate stack space
    pushl %ebx          # Save %ebx
    addl $-12,%esp      # Allocate stack space
    leal -4(%ebp),%ebx  # Compute buf as %ebp-4
    pushl %ebx          # Push buf on stack
    call gets           # Call gets
    . . .

```

Buffer Overflow Stack Example

```

unix> gdb bufdemo
(gdb) break echo
Breakpoint 1 at 0x8048583
(gdb) run
Breakpoint 1, 0x8048583 in echo ()
(gdb) print /x *(unsigned *)$ebp
$1 = 0xbffff8f8
(gdb) print /x *((unsigned *)$ebp + 1)
$3 = 0x804864d
    
```

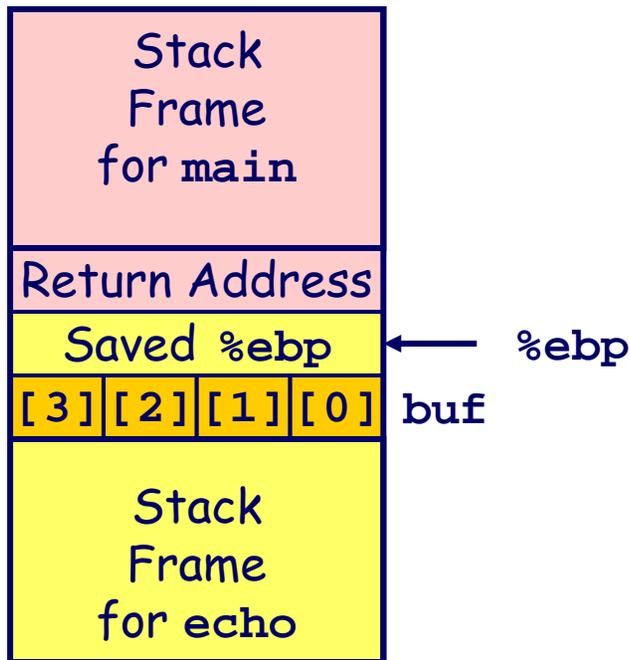

```

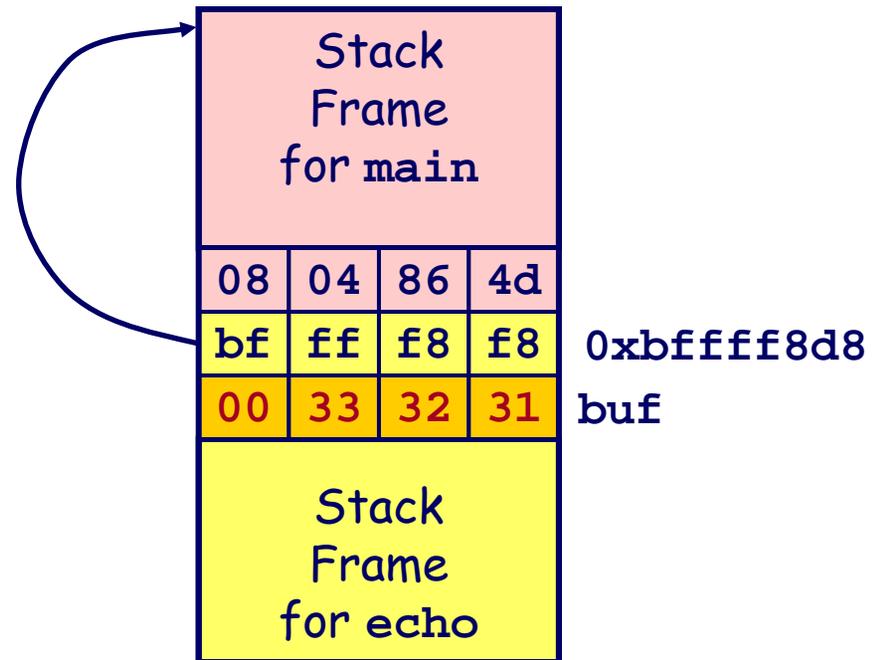

8048648: call 804857c <echo>
804864d: mov 0xffffffe8(%ebp),%ebx # Return Point
    
```

Buffer Overflow Example #1

Before Call to gets

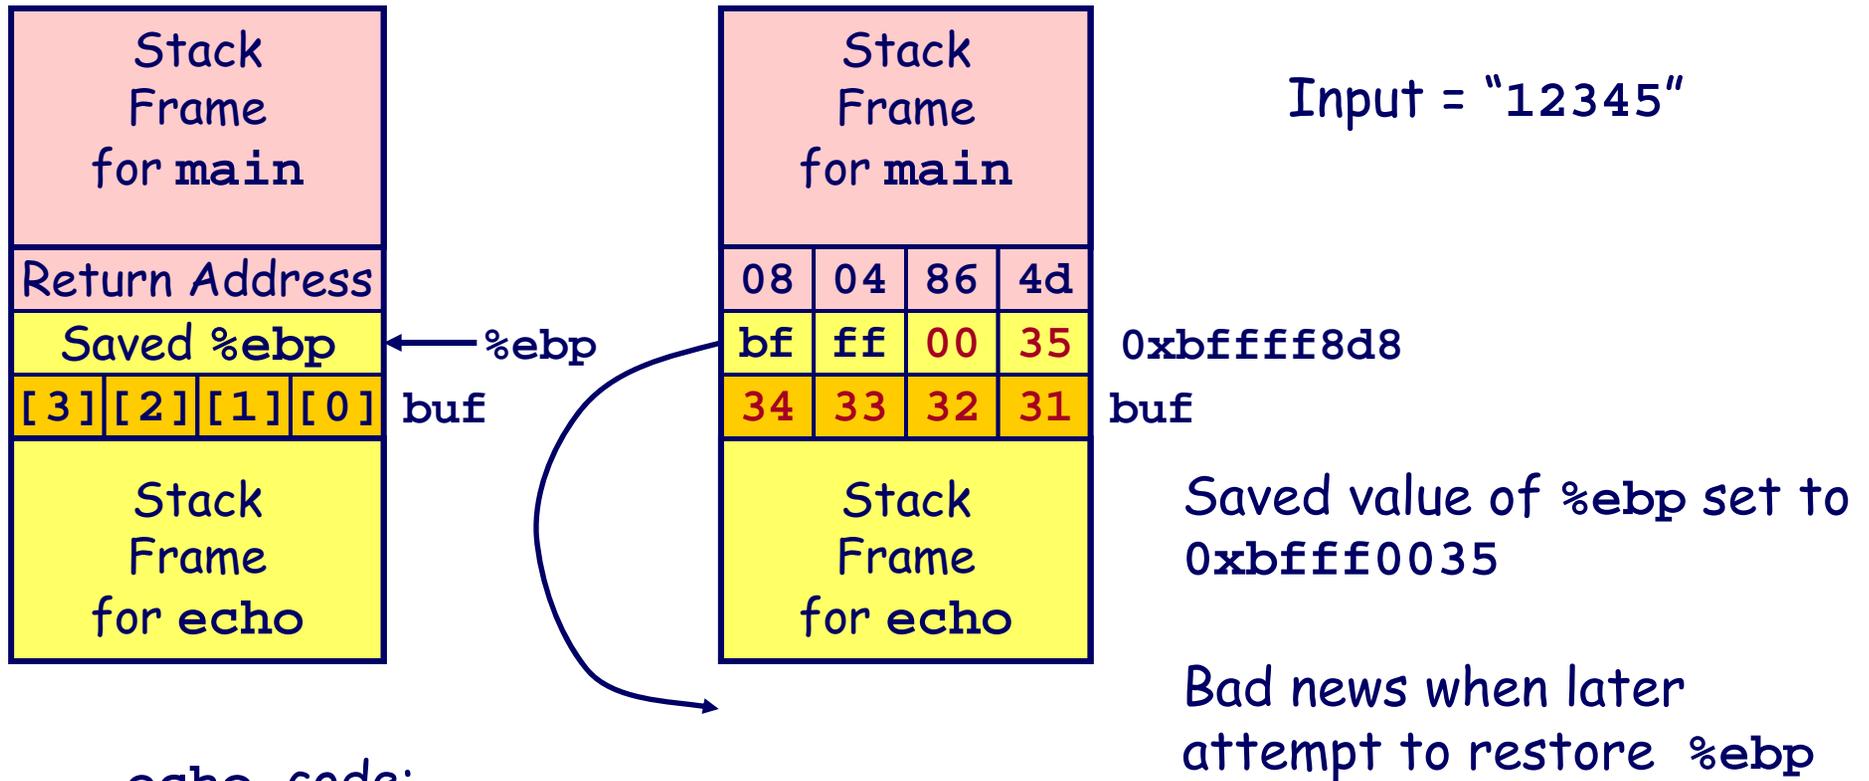

Input = "123"

No Problem

Buffer Overflow Stack Example #2

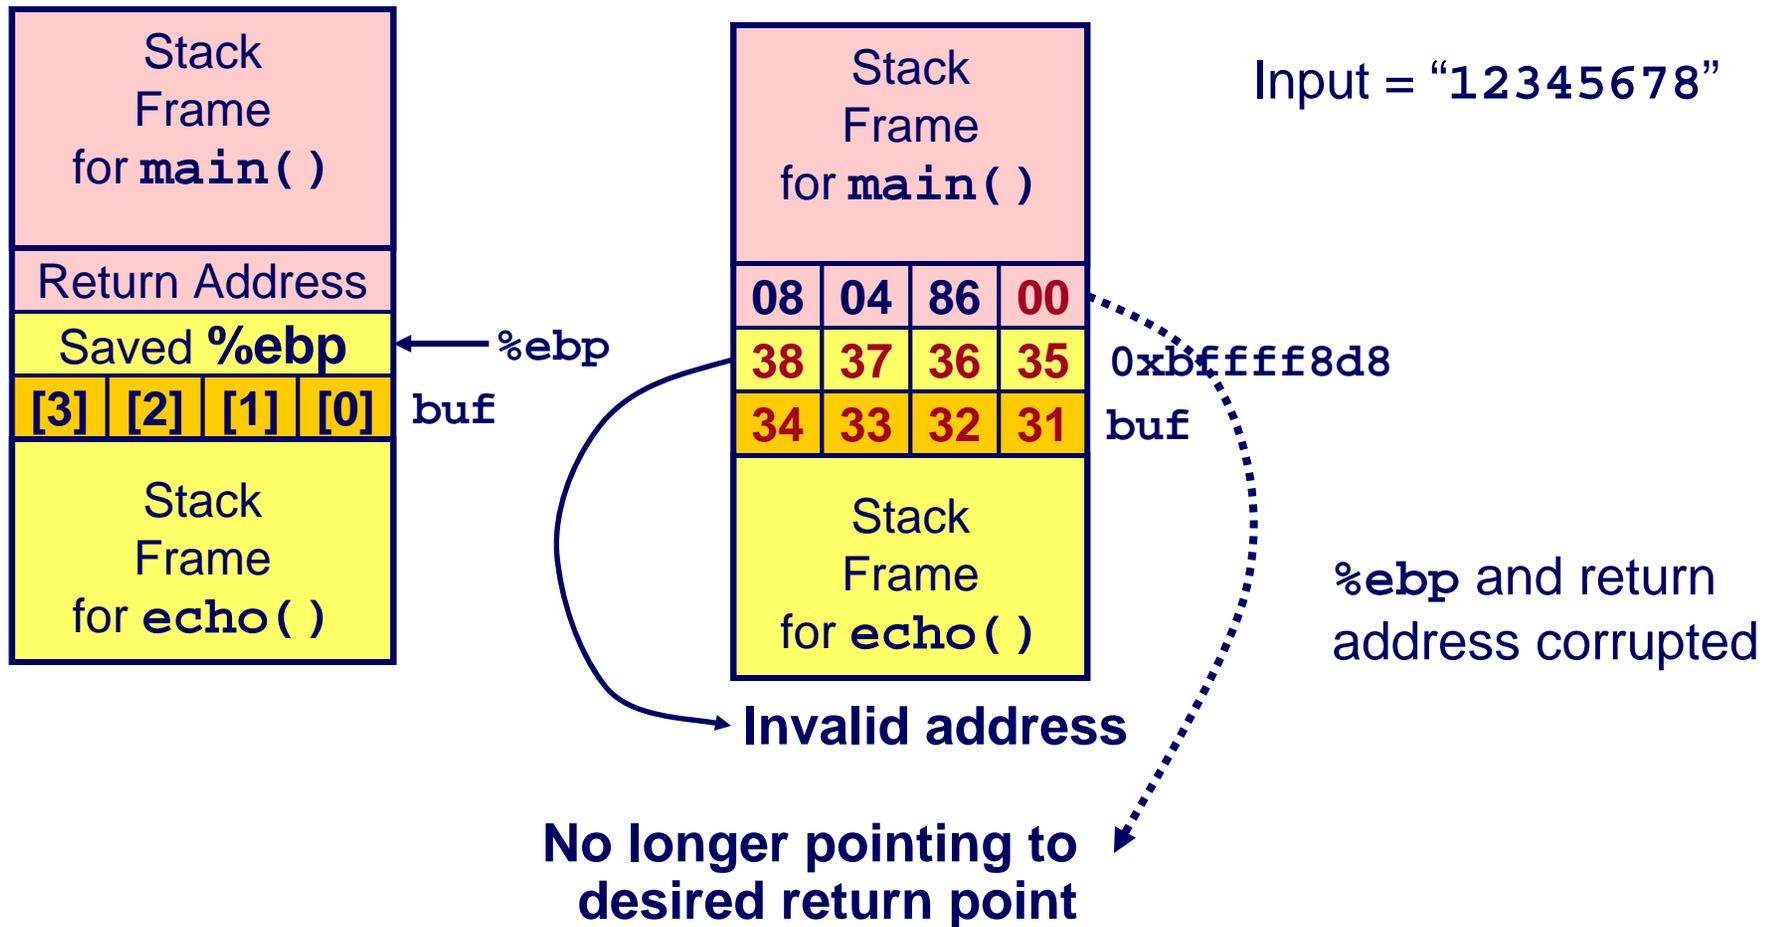

echo code:

```

8048592: push    %ebx
8048593: call   80483e4 <_init+0x50> # gets
8048598: mov    0xffffffffe8(%ebp),%ebx
804859b: mov    %ebp,%esp
804859d: pop   %ebp      # %ebp gets set to invalid value
804859e: ret
    
```

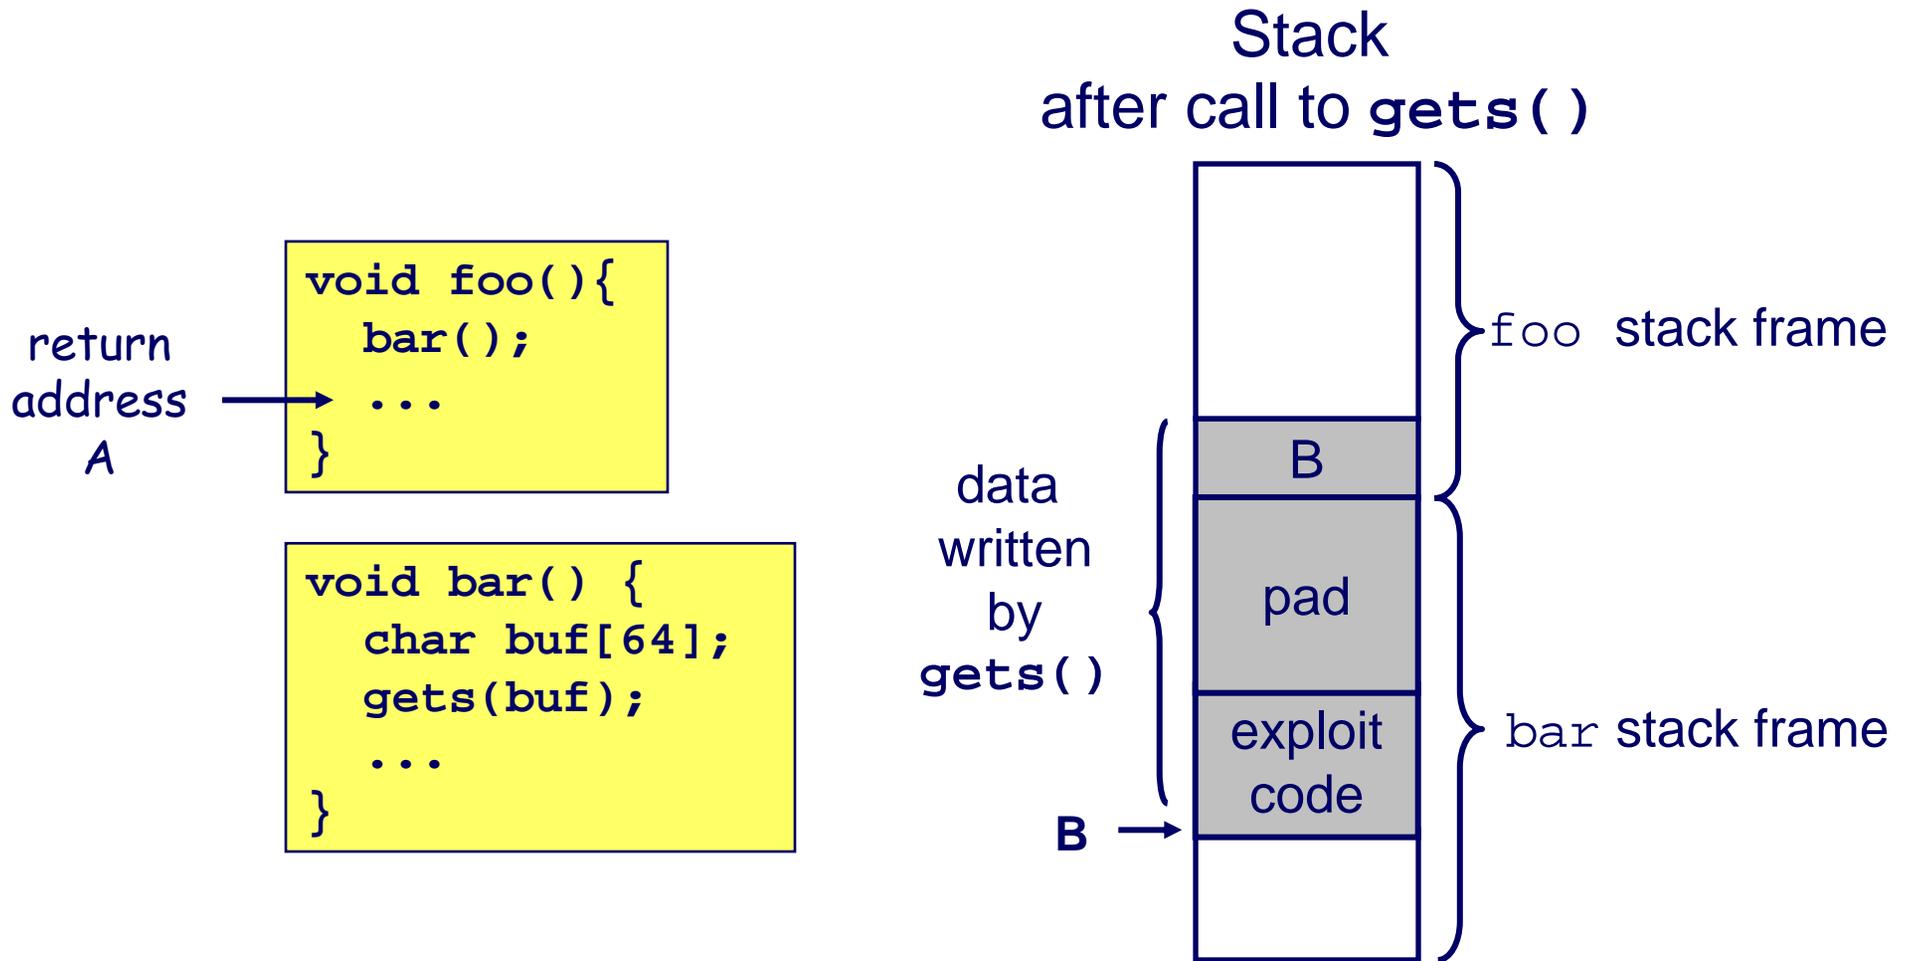

Buffer Overflow Stack Example #3

```

8048648: call 804857c <echo>
804864d: mov 0xffffffe8(%ebp),%ebx # Return Point
    
```

Malicious Use of Buffer Overflow

- Input string contains byte representation of executable code
- Overwrite return address with address of buffer
- When `bar()` executes `ret`, will jump to exploit code

Exploits Based on Buffer Overflows

Buffer overflow bugs allow remote machines to execute arbitrary code on victim machines.

Internet worm

- Early versions of the finger server (fingerd) used `gets()` to read the argument sent by the client:
 - `finger droh@cs.cmu.edu`
- Worm attacked fingerd server by sending phony argument:
 - `finger "exploit-code padding new-return-address"`
 - exploit code: executed a root shell on the victim machine with a direct TCP connection to the attacker.

Summary

Arrays in C

- Contiguous allocation of memory
- Pointer to first element
- No bounds checking

Structures

- Allocate bytes in order declared
- Pad in middle and at end to satisfy alignment

Unions

- Overlay declarations
- Way to circumvent type system

Buffer Overflow

- Overrun stack state with externally supplied data
- Potentially contains executable code
