Shared Variables in Threaded C Programs

Question: Which variables in a threaded C program are shared variables?
- The answer is not as simple as “global variables are shared” and “stack variables are private”.

Requires answers to the following questions:
- What is the memory model for threads?
- How are variables mapped to memory instances?
- How many threads reference each of these instances?

Example of Threads Accessing Another Thread’s Stack

```c
char **ptr; /* global */

int main()
{
    int i;
    pthread_t tid;
    char *msgs[N] = {
        "Hello from foo",
        "Hello from bar"
    };
    ptr = msgs;
    for (i = 0; i < 2; i++)
        pthread_create(&tid, NULL,
                       thread, (void *)i);
    pthread_exit(NULL);
}

/* thread routine */
void *thread(void *vargp)
{
    int myid = (int) vargp;
    static int svar = 0;

    printf("[%d]: %s (svar=%d)\n", myid, ptr[myid], ++svar);
}
```

Peer threads access main thread’s stack indirectly through global ptr variable
Mapping Variables to Mem. Instances

Global var: 1 instance (ptr [data])

char **ptr; /* global */

Local automatic vars: 1 instance (i.m, msgs.m)

int main()
{
    int i;
    pthread_t tid;
    char *msgs[N] = {
        "Hello from foo",
        "Hello from bar"
    };
    ptr = msgs;
    for (i = 0; i < 2; i++)
        Pthread_create(&tid,
                        NULL,
                        thread,
                        (void *)i);
    Pthread_exit(NULL);
}

/* thread routine */
void *thread(void *vargp)
{
    int myid = (int)vargp;
    static int svar = 0;
    printf("[%d]: %s (svar=%d)\n",
           myid, ptr[myid], ++svar);
}

Local static var: 1 instance (svar [data])

Shared Variable Analysis

Which variables are shared?

<table>
<thead>
<tr>
<th>Variable</th>
<th>Referenced by main thread?</th>
<th>Referenced by peer thread 0?</th>
<th>Referenced by peer thread 1?</th>
</tr>
</thead>
<tbody>
<tr>
<td>ptr</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
</tr>
<tr>
<td>svar</td>
<td>no</td>
<td>yes</td>
<td>yes</td>
</tr>
<tr>
<td>i.m</td>
<td>yes</td>
<td>no</td>
<td>no</td>
</tr>
<tr>
<td>msgs.m</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
</tr>
<tr>
<td>myid.p0</td>
<td>no</td>
<td>yes</td>
<td>no</td>
</tr>
<tr>
<td>myid.pl</td>
<td>no</td>
<td>no</td>
<td>yes</td>
</tr>
</tbody>
</table>

Answer: A variable x is shared iff multiple threads reference at least one instance of x. Thus:
- ptr, svar, and msgs are shared.
- i and myid are NOT shared.

badcnt.c: An Improperly Synchronized Threaded Program

/* shared */
volatile unsigned int cnt = 0;
#define NITERS 100000000

int main()
{
    pthread_t tid1, tid2;
    Pthread_create(&tid1, NULL,
                    count, NULL);
    Pthread_create(&tid2, NULL,
                    count, NULL);
    Pthread_join(tid1, NULL);
    Pthread_join(tid2, NULL);
    if (cnt != (unsigned)NITERS*2)
        printf("BOOM! cnt=%d\n", cnt);
    else
        printf("OK cnt=%d\n", cnt);
}

/* thread routine */
void *count(void *arg)
{
    int i;
    for (i=0; i<NITERS; i++)
        cnt++;
    return NULL;
}

Concurrent Execution

Key idea: In general, any sequentially consistent interleaving is possible, but some are incorrect!
- $i_i$ denotes that thread $i$ executes instruction $i$
- $%eax_i$ is the contents of $%eax$ in thread $i$'s context

<table>
<thead>
<tr>
<th>i (thread)</th>
<th>instr</th>
<th>%eax_1</th>
<th>%eax_2</th>
<th>cnt</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>H_1</td>
<td>-</td>
<td>-</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>L_1</td>
<td>0</td>
<td>-</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>U_1</td>
<td>1</td>
<td>-</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>S_1</td>
<td>1</td>
<td>-</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>H_2</td>
<td>-</td>
<td>-</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>L_2</td>
<td>-</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>U_2</td>
<td>-</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>S_2</td>
<td>-</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>T_2</td>
<td>-</td>
<td>2</td>
<td>2</td>
</tr>
</tbody>
</table>
| 1          | T_1   | 1      | -      | 2   | OK

Concurrent Execution (cont)

Incorrect ordering: two threads increment the counter, but the result is 1 instead of 2.

<table>
<thead>
<tr>
<th>i (thread)</th>
<th>instr</th>
<th>%eax_1</th>
<th>%eax_2</th>
<th>cnt</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>H_1</td>
<td>-</td>
<td>-</td>
<td>0</td>
</tr>
<tr>

<td>T_2</td>
<td>-</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>
| 1          | T_1   | 1      | -      | 2   | Oops!

Concurrent Execution (cont)

How about this ordering?

<table>
<thead>
<tr>
<th>i (thread)</th>
<th>instr</th>
<th>%eax_1</th>
<th>%eax_2</th>
<th>cnt</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>H_1</td>
<td>-</td>
<td>-</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>L_1</td>
<td>0</td>
<td>-</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>H_2</td>
<td>-</td>
<td>-</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>L_2</td>
<td>-</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>U_2</td>
<td>-</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>S_2</td>
<td>-</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>T_2</td>
<td>-</td>
<td>2</td>
<td>2</td>
</tr>
</tbody>
</table>
| 1          | T_1   | 1      | -      | 2   | OK

We can clarify our understanding of concurrent execution with the help of the progress graph

Beware of Optimizing Compilers!

Code From Book

```c
#define NITERS 100000000
/* shared counter variable */
unsigned int cnt = 0;

/* thread routine */
void *count(void *arg) {
    int i;
    for (i = 0; i < NITERS; i++)
        cnt++;
    return NULL;
}
```

Generated Code

```
movl cnt, %ecx
movl $99999999, %eax
.L6:
    leal 1(%ecx), %edx
    decl %eax
    movl %edx, %ecx
    jns .L6
    movl %edx, cnt
```

- Compiler moved access to `cnt` out of loop
- Only shared accesses to `cnt` occur before loop (read) or after (write)
- Multiple threads could be trying to update within their iterations

We can clarify our understanding of concurrent execution with the help of the progress graph

```
  0   1   2   3   4   5   6   7   8   9   10  11  12  13  14  15
  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
  H  | L  | U  | S  | T  | L  | U  | S  | T  | H  | L  | U  | S  | T  | L |
  1  | 2  | 1  | 2  | 1  | 2  | 1  | 2  | 1  | 2  | 1  | 2  | 1  | 2  | 1 |
  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
```

- Global variable `cnt` shared between threads
- Many threads could be trying to update within their iterations
- What are possible program outcomes?
Controlling Optimizing Compilers!

Revised Book Code

```c
#define NITERS 100000000

/* shared counter variable */
volatile unsigned int cnt = 0;

/* thread routine */
void *count(void *arg)
{
    int i;
    for (i = 0; i < NITERS; i++)
        cnt++;
    return NULL;
}
```

Shared variable read and written each iteration

Declaring variable as volatile forces it to be kept in memory

Progress Graphs

A progress graph depicts the discrete execution state space of concurrent threads.

Each axis corresponds to the sequential order of instructions in a thread.

Each point corresponds to a possible execution state (Inst₁, Inst₂).

E.g., (L₁, S₂) denotes state where thread 1 has completed L₁ and thread 2 has completed S₂.

Trajectories in Progress Graphs

A trajectory is a sequence of legal state transitions that describes one possible concurrent execution of the threads.

Example:
H₁, L₁, U₁, H₂, L₂, S₁, T₁, U₂, S₂, T₂

Critical Sections and Unsafe Regions

L, U, and S form a critical section with respect to the shared variable cnt.

Instructions in critical sections (wrt to some shared variable) should not be interleaved.

Sets of states where such interleaving occurs form unsafe regions.
Safe and Unsafe Trajectories

**Def:** A trajectory is **safe** iff it doesn’t touch any part of an unsafe region.

**Claim:** A trajectory is correct (wrt cnt) iff it is safe.

![Diagram of trajectories and regions]

Semaphores

**Question:** How can we guarantee a safe trajectory?

- We must **synchronize** the threads so that they never enter an unsafe state.

**Classic solution:** Dijkstra's P and V operations on semaphores.

- **Semaphore**: non-negative integer synchronization variable.
  - `P(s): [while (s == 0) wait(); s--; ]`
  - Dutch for "Proberen" (test)
  - `V(s): [s++; ]`
  - Dutch for "Verhogen" (increment)

**OS guarantees** that operations between brackets [] are executed indivisibly.
- Only one P or V operation at a time can modify s.
- When while loop in P terminates, only that P can decrement s.

**Semaphore invariant:** `(s >= 0)`

Safe Sharing with Semaphores

Here is how we would use P and V operations to synchronize the threads that update cnt.

```c
/* Semaphore s is initially 1 */
/* Thread routine */
void *count(void *arg)
{
    int i;
    for (i=0; i<NITERS; i++) {
        P(s);
        cnt++;
        V(s);
    }
    return NULL;
}
```

Semaphores

**Safe Sharing With Semaphores**

Provide mutually exclusive access to shared variable by surrounding critical section with P and V operations on semaphore s (initially set to 1).

Semaphore invariant creates a **forbidden region** that encloses unsafe region and is never touched by any trajectory.
Wrappers on POSIX Semaphores

/* Initialize semaphore sem to value */
/* pshared=0 if thread, pshared=1 if process */
void Sem_init(sem_t *sem, int pshared, unsigned int value) {
    if (sem_init(sem, pshared, value) < 0)
        unix_error("Sem_init");
}

/* P operation on semaphore sem */
void P(sem_t *sem) {
    if (sem_wait(sem))
        unix_error("P");
}

/* V operation on semaphore sem */
void V(sem_t *sem) {
    if (sem_post(sem))
        unix_error("V");
}

Sharing With POSIX Semaphores

/* properly sync'd counter program */
#include "csapp.h"
#define NITERS 10000000
volatile unsigned int cnt;

int main() {
    pthread_t tid1, tid2;
    Sem_init(&sem, 0, 1); /* sem=1 */
   ...
    if (cnt != (unsigned)NITERS*2)
        printf("BOOM! cnt=%d\n", cnt);
    else
        printf("OK cnt=%d\n", cnt);
    exit(0);
}

Signaling With Semaphores

Common synchronization pattern:
- Producer waits for slot, inserts item in buffer, and "signals" consumer.
- Consumer waits for item, removes it from buffer, and "signals" producer.
- "signals" in this context has nothing to do with Unix signals

Examples
- Multimedia processing:
  - Producer creates MPEG video frames, consumer renders the frames
- Event-driven graphical user interfaces
  - Producer detects mouse clicks, mouse movements, and keyboard hits and inserts corresponding events in buffer.
  - Consumer retrieves events from buffer and paints the display.

Producer-Consumer on a Buffer That Holds One Item

/* buf1.c - producer-consumer on 1-element buffer */
#include "csapp.h"
#define NITERS 5

int main() {
    pthread_t tid_producer;
    pthread_t tid_consumer;
    Sem_init(&shared.empty, 0, 1);
    Sem_init(&shared.full, 0, 0);
   ...
    if (cnt != (unsigned)NITERS*2)
        printf("BOOM! cnt=%d\n", cnt);
    else
        printf("OK cnt=%d\n", cnt);
    exit(0);
}
Producer-Consumer (cont)

Initially: empty = 1, full = 0.

```c
/* producer thread */
void *producer(void *arg) {
    int i, item;
    for (i=0; i<NITERS; i++) {
        /* produce item */
        item = i;
        printf("produced %d\n", item);
        /* write item to buf */
        P(&shared.empty);
        shared.buf = item;
        V(&shared.full);
    }
    return NULL;
}

/* consumer thread */
void *consumer(void *arg) {
    int i, item;
    for (i=0; i<NITERS; i++) {
        /* read item from buf */
        P(&shared.full);
        item = shared.buf;
        V(&shared.empty);
        /* consume item */
        printf("consumed %d\n", item);
    }
    return NULL;
}
```

Thread Safety

Functions called from a thread must be thread-safe.

We identify four (non-disjoint) classes of thread-unsafe functions:

- Class 1: Failing to protect shared variables.
- Class 2: Relying on persistent state across invocations.
- Class 3: Returning a pointer to a static variable.
- Class 4: Calling thread-unsafe functions.

Thread-Unsafe Functions

Class 1: Failing to protect shared variables.
- Fix: Use P and V semaphore operations.
- Example: goodcnt.c
- Issue: Synchronization operations will slow down code.
  - e.g., badcnt requires 0.5s, goodcnt requires 7.9s

```c
/* rand - return pseudo-random integer on 0..32767 */
int rand(void) {
    static unsigned int next = 1;
    next = next*1103515245 + 12345;
    return (unsigned int)(next/65536) % 32768;
}

/* srand - set seed for rand() */
void srand(unsigned int seed) {
    next = seed;
}
```

Class 2: Relying on persistent state across multiple function invocations.
- Random number generator relies on static state
  - Fix: Rewrite function so that caller passes in all necessary state.
Thread-Unsafe Functions (cont)

Class 3: Returning a ptr to a static variable.

Fixes:
- 1. Rewrite code so caller passes pointer to struct.
   - Issue: Requires changes in caller and callee.
- 2. Lock-and-copy
   - Issue: Requires only simple changes in caller (and none in callee)
   - However, caller must free memory.

```c
struct hostent
*gethostbyname(char name)
{
    static struct hostent h;
    <contact DNS and fill in h>
    return &h;
}

hostp = Malloc(...));
gethostbyname_r(name, hostp);
```

Thread-Unsafe Functions

Class 4: Calling thread-unsafe functions.

- Calling one thread-unsafe function makes an entire function thread-unsafe.
- Fix: Modify the function so it calls only thread-safe functions

Reentrant Functions

A function is **reentrant** iff it accesses NO shared variables when called from multiple threads.
- Reentrant functions are a proper subset of the set of thread-safe functions.

- NOTE: The fixes to Class 2 and 3 thread-unsafe functions require modifying the function to make it reentrant.

Thread-Safe Library Functions

All functions in the Standard C Library (at the back of your K&R text) are thread-safe.
- Examples: malloc, free, printf, scanf

Most Unix system calls are thread-safe, with a few exceptions:

<table>
<thead>
<tr>
<th>Thread-unsafe function</th>
<th>Class</th>
<th>Reentrant version</th>
</tr>
</thead>
<tbody>
<tr>
<td>asctime</td>
<td>3</td>
<td>asctime_r</td>
</tr>
<tr>
<td>ctime</td>
<td>3</td>
<td>ctime_r</td>
</tr>
<tr>
<td>gethostbyaddr</td>
<td>3</td>
<td>gethostbyaddr_r</td>
</tr>
<tr>
<td>gethostbyname</td>
<td>3</td>
<td>gethostbyname_r</td>
</tr>
<tr>
<td>inet_ntoa</td>
<td>3</td>
<td>(none)</td>
</tr>
<tr>
<td>localtime</td>
<td>3</td>
<td>localtime_r</td>
</tr>
<tr>
<td>rand</td>
<td>2</td>
<td>rand_r</td>
</tr>
</tbody>
</table>
Races

A race occurs when the correctness of the program depends on one thread reaching point x before another thread reaches point y.

```c
/* a threaded program with a race */
int main() {
    pthread_t tid[N];
    int i;
    for (i = 0; i < N; i++)
        Pthread_create(&tid[i], NULL, thread, &i);
    for (i = 0; i < N; i++)
        Pthread_join(tid[i], NULL);
    exit(0);
}
/* thread routine */
void *thread(void *vargp) {
    int myid = *((int *)vargp);
    printf("Hello from thread %d\n", myid);
    return NULL;
}
```

Deadlock

- Processes wait for condition that will never be true

Typical Scenario

- Processes 1 and 2 needs resources A and B to proceed
- Process 1 acquires A, waits for B
- Process 2 acquires B, waits for A
- Both will wait forever!

Deadlocking With POSIX Semaphores

```c
int main()
{
    pthread_t tid[2];
    Sem_init(&mutex[0], 0, 1); /* mutex[0] = 1 */
    Sem_init(&mutex[1], 0, 1); /* mutex[1] = 1 */
    Pthread_create(&tid[0], NULL, count, (void*) 0);
    Pthread_create(&tid[1], NULL, count, (void*) 1);
    Pthread_join(tid[0], NULL);
    Pthread_join(tid[1], NULL);
    printf("cnt=%d\n", cnt);
    exit(0);
}
void *count(void *vargp)
{
    int i;
    int id = (int) vargp;
    for (i = 0; i < NITERS; i++)
    {
        P(&mutex[id]); P(&mutex[1-id]);
        cnt++;
        V(&mutex[id]); V(&mutex[1-id]);
    }
    return NULL;
}
```

Deadlock

Locking introduces the potential for deadlock: waiting for a condition that will never be true.

Any trajectory that enters the deadlock region will eventually reach the deadlock state, waiting for either s₀ or s₁ to become nonzero.

Other trajectories luck out and skirt the deadlock region.

Unfortunate fact: deadlock is often non-deterministic.
Avoiding Deadlock

```c
int main()
{
    pthread_t tid[2];
    Sem_init(&mutex[0], 0, 1); /* mutex[0] = 1 */
    Sem_init(&mutex[1], 0, 1); /* mutex[1] = 1 */
    Pthread_create(&tid[0], NULL, count, (void*) 0);
    Pthread_create(&tid[1], NULL, count, (void*) 1);
    Pthread_join(tid[0], NULL);
    Pthread_join(tid[1], NULL);
    printf("cnt=%d\n", cnt);
    exit(0);
}
```

```c
void *count(void *vargp) {
    int i;
    int id = (int) vargp;
    for (i = 0; i < NITERS; i++) {
        P(&mutex[0]); P(&mutex[1]);
        cnt++; V(&mutex[id]); V(&mutex[1-id]);
    }
    return NULL;
}
```

Threads Summary

Threads provide another mechanism for writing concurrent programs.

Threads are growing in popularity
- Somewhat cheaper than processes.
- Easy to share data between threads.

However, the ease of sharing has a cost:
- Easy to introduce subtle synchronization errors.
- Tread carefully with threads!
