"The course that gives CMU its Zip!"

Structured Data

Sept. 17, 1998

Topics

- **Arrays**
  - Single
  - Nested
- **Pointers**
  - Multilevel Arrays
- **Optimized Array Code**

Basic Data Types

Integral

- Stored & operated on in general registers
- Signed vs. unsigned depends on instructions used

Alpha	Bytes	C
byte	1	[unsigned] `char`
word	2	[unsigned] `short`
long word	4	[unsigned] `int`
quad word	8	[unsigned] `long int`, pointers

Floating Point

- Stored & operated on in floating point registers
- Special instructions for four different formats (only 2 we care about)

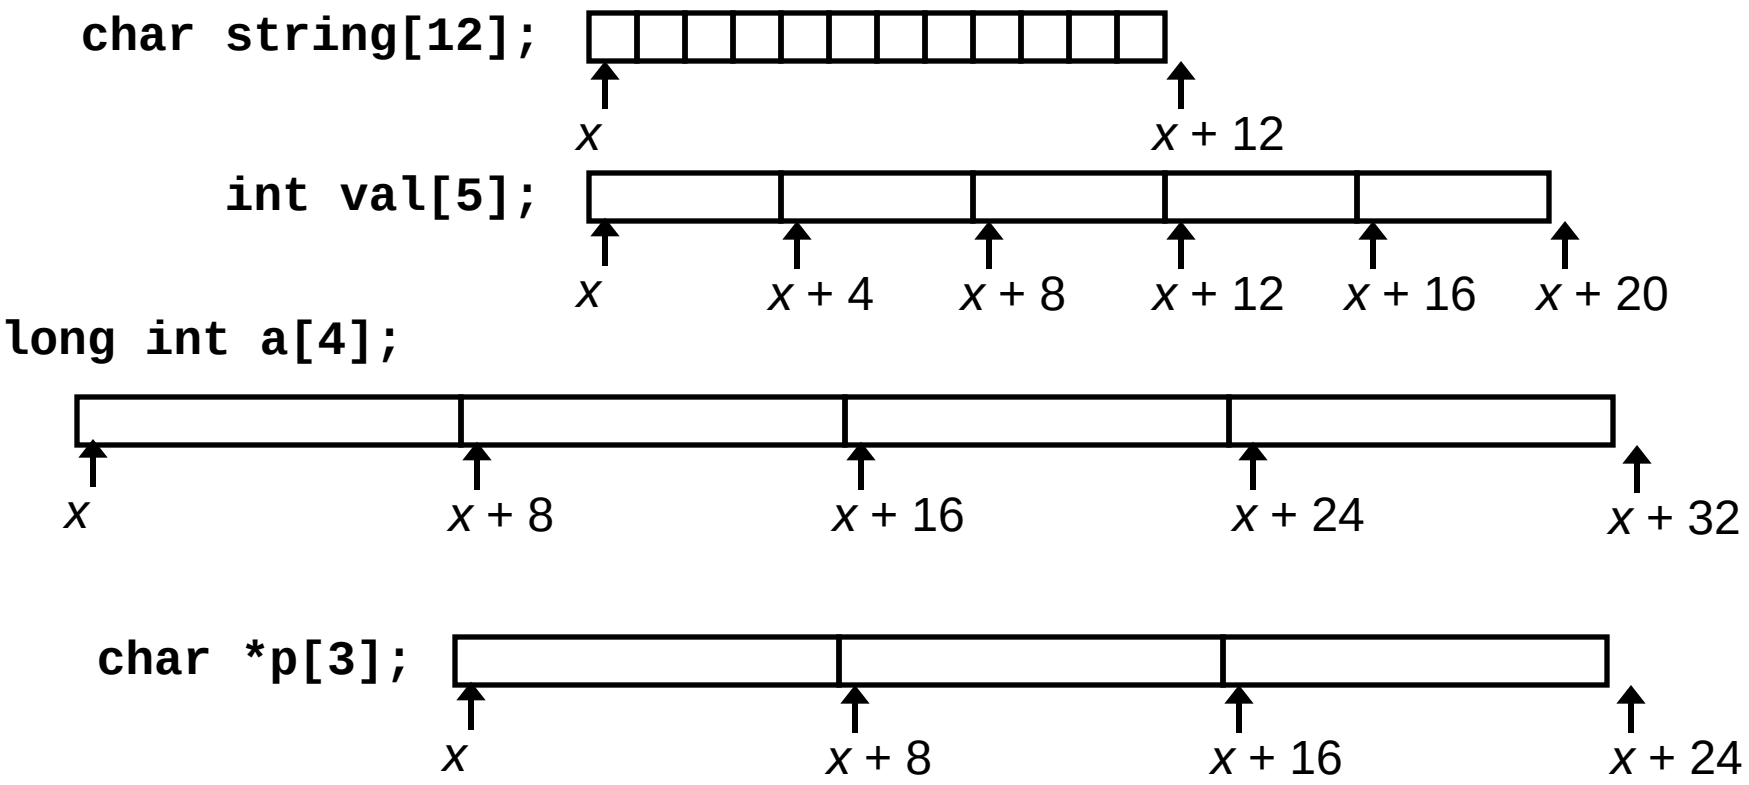
Alpha	Bytes	C
S_floating	4	`float`
T_floating	8	`double`

Array Allocation

Basic Principle

T **`A[`***L***`];`**

- **Array of data type *T* and length *L***
- **Contiguously allocated region of *L* `*` `sizeof(`*T*`)` bytes**

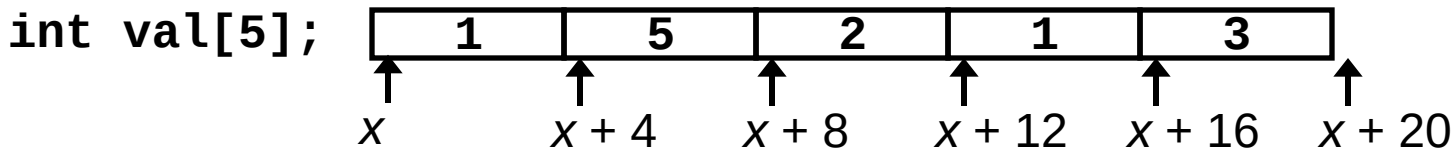


Array Access

Basic Principle

T **A[***L***];**

- **Array of data type *T* and length *L***
- **Identifier A can be used as a pointer to starting element of the array**

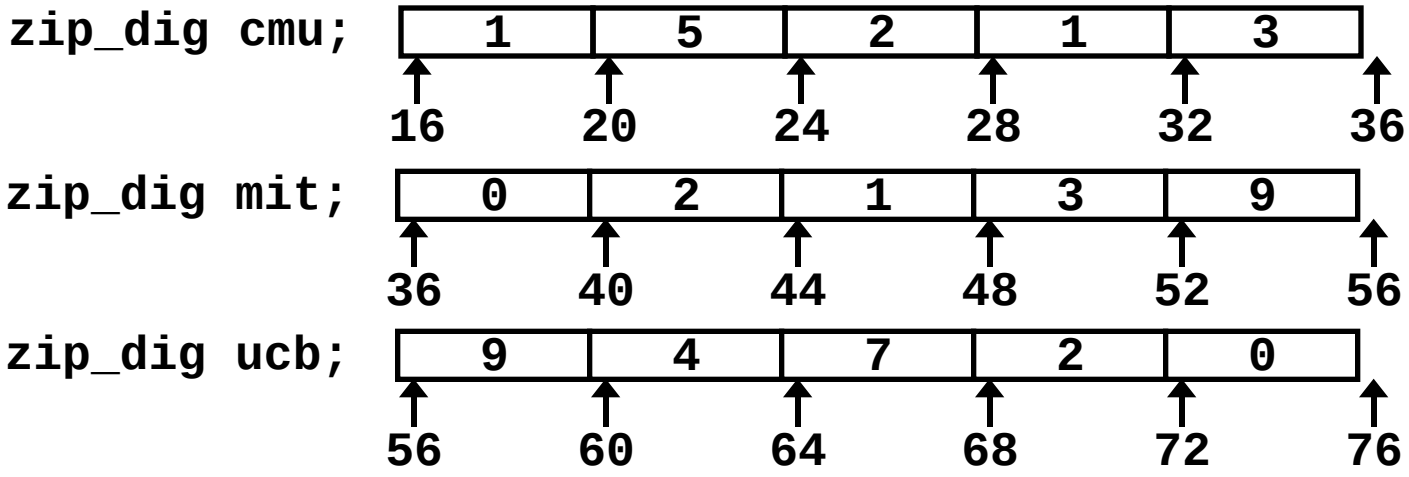


Reference	Type	Value
`val[4]`	`int`	**3**
`val`	`int *`	*x*
`val+1`	`int *`	*x* **+ 4**
`&val[2]`	`int *`	*x* **+ 8**
`val[5]`	`int`	**??**
`*(val+1)`	`int`	**5**
`val + i`	`int *`	*x* **+ 4** *i*

Array Example

```
typedef int zip_dig[5];

zip_dig cmu = { 1, 5, 2, 1, 3 };
zip_dig mit = { 0, 2, 1, 3, 9 };
zip_dig ucb = { 9, 4, 7, 2, 0 };
```



Notes

- **Declaration "`zip_dig cmu`" equivalent to "`int cmu[5]`"**
- **Example arrays were allocated in successive 20 byte blocks**
  - Not guaranteed to happen in general

Array Accessing Example

Computation

- **Register $16 contains starting address of array**
- **Register $17 contains array index**
- **Desired digit at `4*$17 + $16`**
- **Use instruction `s4addq`**

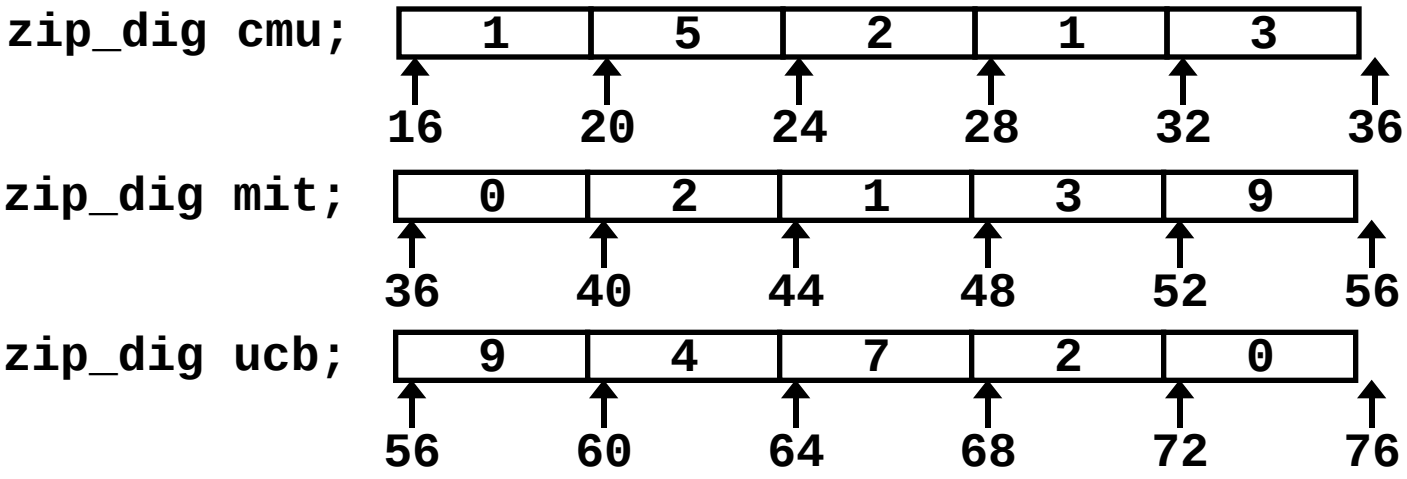
```
int get_digit
  (zip_dig z, int dig)
{
  return z[dig];
}
```

Memory Access

- **Instruction `ldl` used since stored value is `int`, rather than `long int`**
  - Alpha “long word”

```
s4addq $17,$16,$17 # z + 4*dig
ldl $0,0($17)      # z[dig]
ret $31,($26),1    # return
```

Referencing Examples



Code Does Not Do Any Bounds Checking!

Reference	Address	Value	Guaranteed?
`mit[3]`	`36 + 4* 3 = 48`	3	Yes
`mit[5]`	`36 + 4* 5 = 56`	9	No
`mit[-1]`	`36 + 4*-1 = 32`	3	No
`cmu[15]`	`16 + 4*15 = 76`	??	No

- **Out of range behavior implementation-dependent**
  - No guranteed relative allocation of different arrays

Array Loop Example

```
int zd2int(zip_dig z)
{
  int i;
  int zi = 0;
  for (i = 0; i < 5; i++) {
    zi = 10 * zi + z[i];
  }
  return zi;
}
```

Registers

```
$16   z
$0    zi
$3    i
```

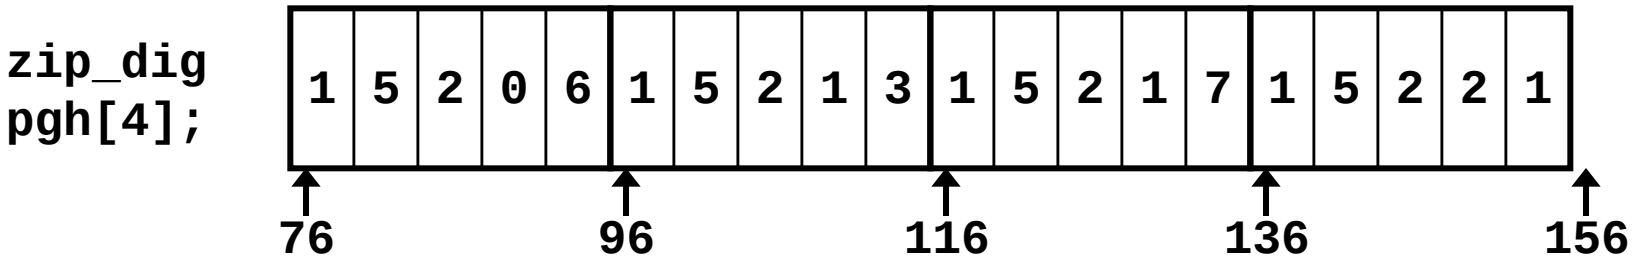
Computations

- 10 * *x* **implemented as** (4+1) * *x* + (4+1) * *x*
  - Avoids use of slow multiply instruction
- **Digit access as `4*$3 + $16`**

```
   bis $31,$31,$0    # zi = 0
   bis $31,$31,$3    # i = 0
$61:                 # loop
   s4addl $0,$0,$2   # 5*zi
   addq $2,$2,$2     # 10*zi
   s4addq $3,$16,$1  # &z[i]
   ldl $1,0($1)      # z[i]
   addl $2,$1,$0     # z[i]=10*zi+z[i]
   addl $3,1,$3      # i++
   cmple $3,4,$1     # if i<=4
   bne $1,$61        # goto loop
   ret $31,($26),1
```

Nested Array Example

```
#define PCOUNT 4
zip_dig pgh[PCOUNT] =
  {{1, 5, 2, 0, 6},
   {1, 5, 2, 1, 3 },
   {1, 5, 2, 1, 7 },
   {1, 5, 2, 2, 1 }};
```



- **Declaration "`zip_dig pgh[4]`" equivalent to "`int pgh[4][5]`"**
  - Variable **`pgh`** denotes array of 4 elements
    - » Allocated contiguously
  - Each element is an array of 5 **`int`**'s
    - » Allocated contiguously
- **"Row-Major" ordering of all elements guaranteed**

Nested Array Allocation

Declaration

T **A[*R*][*C*];**

- **Array of data type *T***
- ***R* rows**
- ***C* columns**
- **Type *T* element requires *K* bytes**

```
a[0][0]   • • •   a[0][C-1]
   •                 •
   •                 •
   •                 •
a[R-1][0] • • • a[R-1][C-1]
```

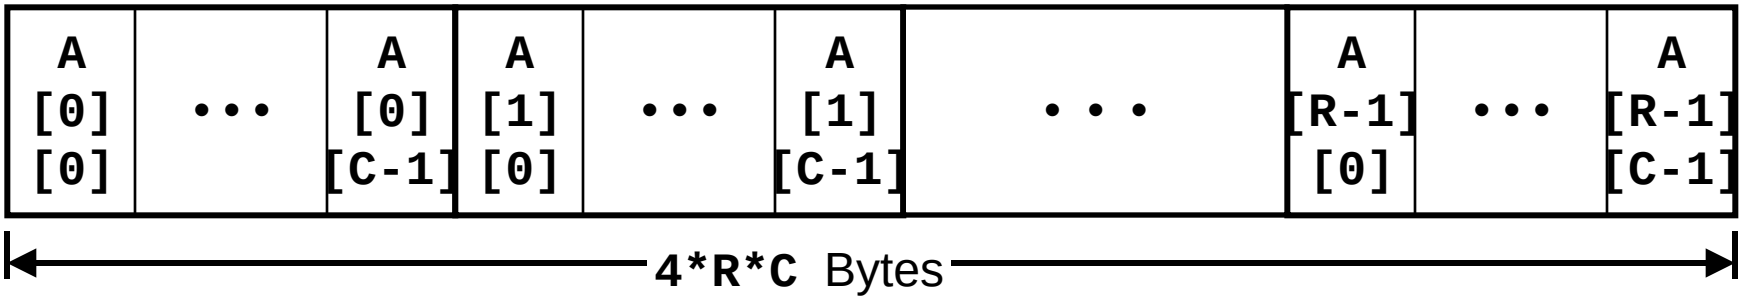
Array Size

- ***R* * *C* * *K* bytes**

Arrangement

- Row-Major Ordering

```
int A[R][C];
```

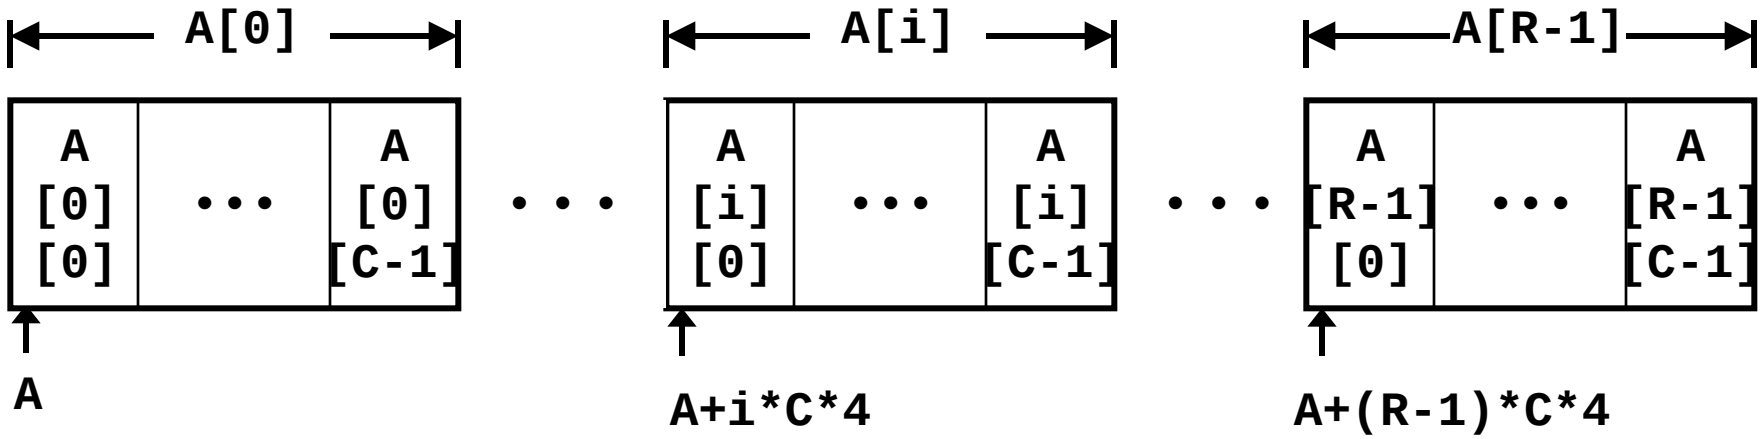


Nested Array Row Access

Row Vectors

- **`A[i]` is array of *C* elements**
- **Each element of type *T***
- **Starting address `A` + *i* * *C* * *K***

```
int A[R][C];
```



Nested Array Row Access Code

Row Vector

- `pgh[index]` is array of 5 `int`'s
- Starting address `pgh+20*index`

Code

- Computes and returns address

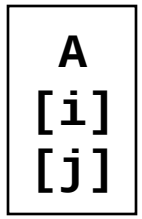
```
int *get_pgh_zip
  (int index)
{
  return pgh[index];
}
```

```
get_pgh_zip..ng:
   s4addq $16,$16,$16  # 5*index
   lda $0,pgh          # pgh
   s4addq $16,$0,$0    # 20*index + pgh
   ret $31,($26),1     # return computed address
```

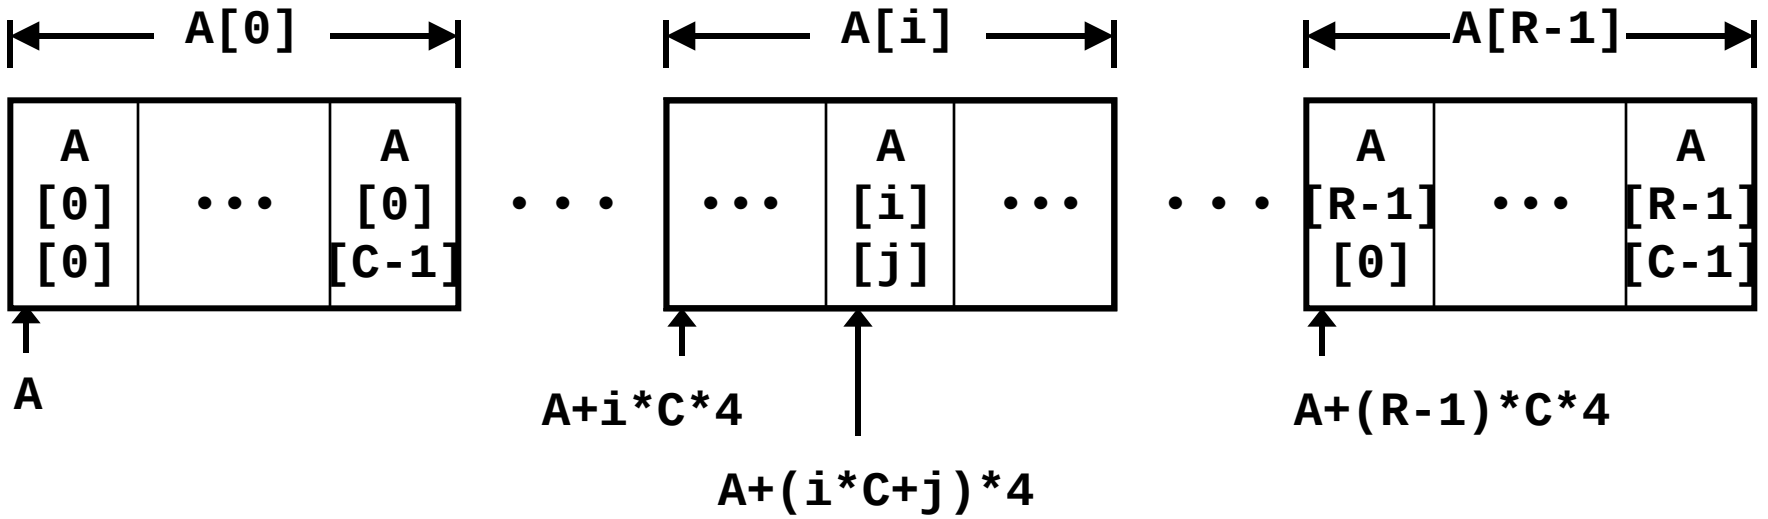
Nested Array Element Access

Array Elements

- **`A[i][j]` is element of type *T***
- **Address `A +` (*i* * *C* + *j*) * *K***



```
int A[R][C];
```



Nested Array Element Access Code

Array Elements

- `pgh[index][dig]` is `int`
- Address:

  `pgh + 20*index + 4*dig`

```
int get_pgh_digit
  (int index, int dig)
{
  return pgh[index][dig];
}
```

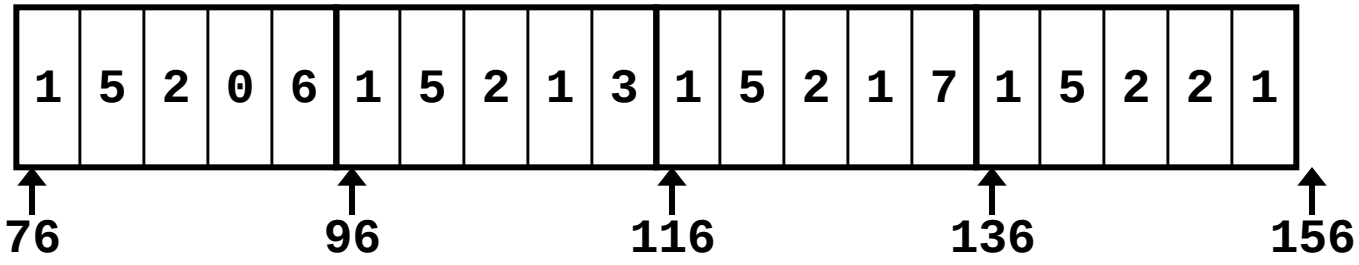
Code

- Computes address
- Loads and returns value

```
get_pgh_digit..ng:
   s4addq $16,$16,$16  # 5 *index
   lda $1,pgh          # pgh
   s4addq $16,$1,$16   # pgh + 20*index
   s4addq $17,$16,$17  # pgh+20*index+4*dig
   ldl $0,0($17)       # pgh[index][dig]
   ret $31,($26),1
```

Strange Referencing Examples

```
zip_dig
pgh[4];
```



Reference	Address	Value	Guaranteed?
pgh[3][3]	76+20*3+4*3 = 148	2	Yes
pgh[2][5]	76+20*2+4*5 = 136	1	Yes
pgh[2][-1]	76+20*2+4*-1 = 112	3	Yes
pgh[4][-1]	76+20*4+4*-1 = 152	1	Yes
pgh[0][19]	76+20*0+4*19 = 152	1	Yes
pgh[0][-1]	76+20*0+4*-1 = 72	??	No

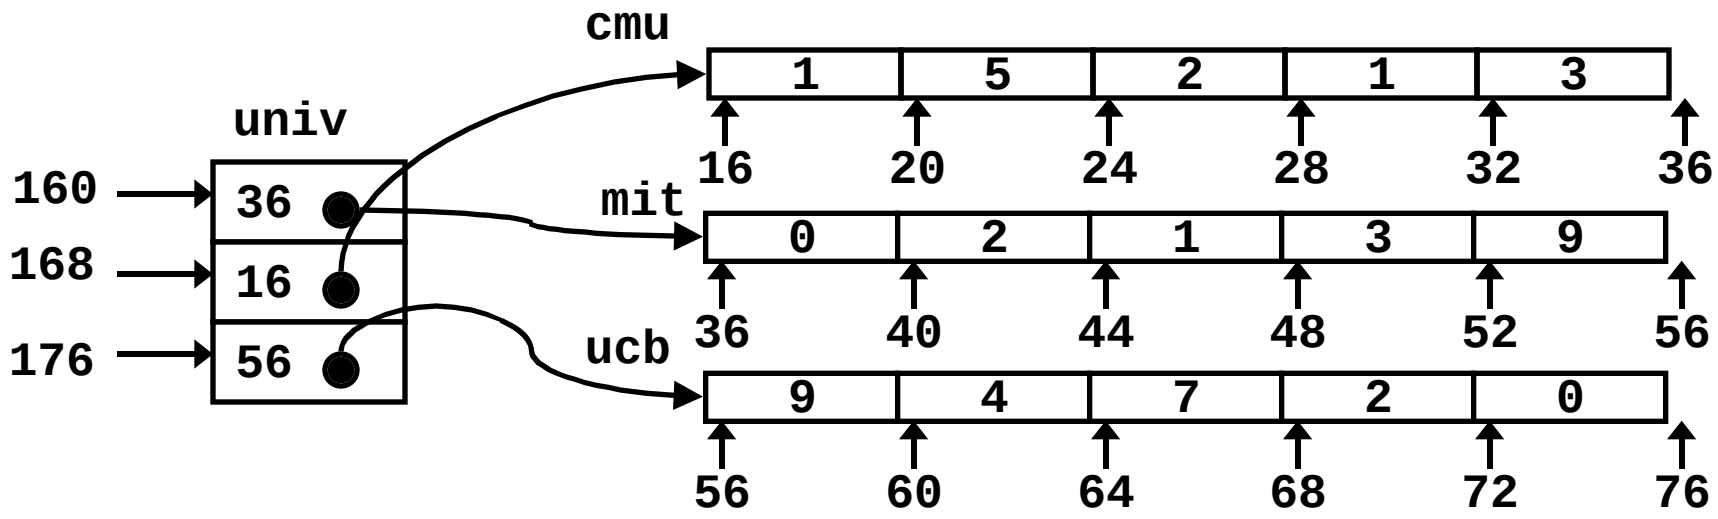
- Code does not do any bounds checking
- Ordering of elements within array guaranteed

Multi-Level Array Example

- **Variable `univ` denotes array of 3 elements**
- **Each element is a pointer**
  - 8 bytes
- **Each pointer points to array of `int`'s**

```
zip_dig cmu = { 1, 5, 2, 1, 3 };
zip_dig mit = { 0, 2, 1, 3, 9 };
zip_dig ucb = { 9, 4, 7, 2, 0 };
```

```
#define UCOUNT 3
int *univ[UCOUNT] = {mit, cmu, ucb};
```



Referencing “Row” in Multi-Level Array

Row Vector

- `univ[index]` is pointer to array of `int`’s
- Starting address `Mem[univ+8*index]`

```
int* get_univ_zip(int index)
{
  return univ[index];
}
```

Code

- Computes address within `univ`
- Loads and returns pointer

```
get_univ_zip..ng:
   lda $1,univ         # univ
   s8addq $16,$1,$16   # univ+8*index
   ldq $0,0($16)       # univ[index]
   ret $31,($26),1
```

Accessing Element in Multi-Level Array

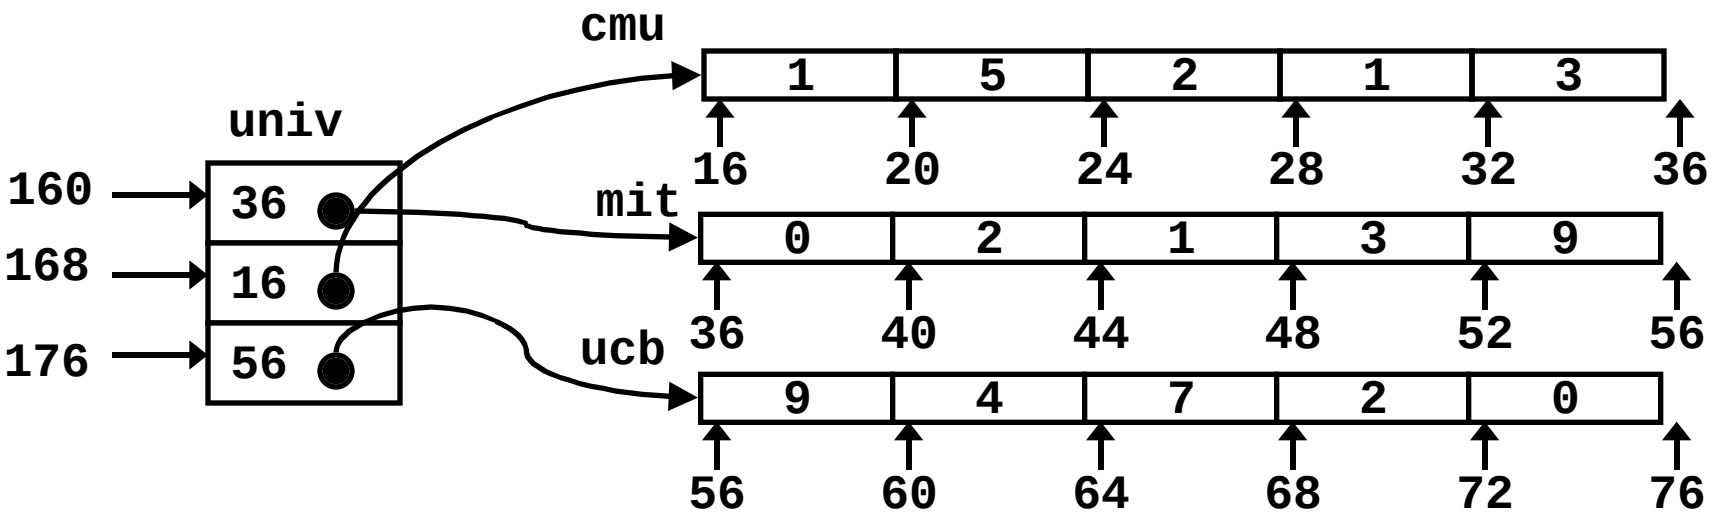
Computation

- **Element access**
  `Mem[Mem[univ+8*index]+4*dig]`
- **Must do two loads**
  - First get pointer to row array
  - Then access element within array

```
int get_univ_digit
  (int index, int dig)
{
  return univ[index][dig];
}
```

```
get_univ_digit..ng:
   lda $1,univ        # univ
   s8addq $16,$1,$16  # univ+8*index
   ldq $1,0($16)      # univ[index]
   s4addq $17,$1,$17  # univ[index]+4*dig
   ldl $0,0($17)      # univ[index][dig]
   ret $31,($26),1
```

Strange Referencing Examples



Reference	Address	Value	Guaranteed?
univ[2][3]	56+4*3 = 68	2	Yes
univ[1][5]	16+4*5 = 36	0	No
univ[2][-1]	56+4*-1 = 52	9	No
univ[3][-1]	??	??	No
univ[1][12]	16+4*12 = 64	7	No

- Code does not do any bounds checking
- Ordering of elements in different arrays not guaranteed

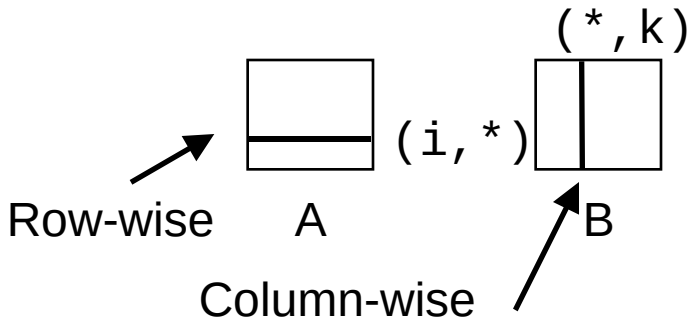
Using Nested Arrays

Strengths

- **C compiler handles doubly subscripted arrays**
- **Generates very efficient code**
  - Avoids multiply in index computation

Limitation

- **Only works if have fixed array size**



```
#define N 16
typedef int fix_matrix[N][N];
```

```
/* Compute element i,k of
   fixed matrix product */
int fix_prod_ele
(fix_matrix a, fix_matrix b,
 long int i, long int k)
{
  long int j;
  int result = 0;
  for (j = 0; j < N; j++)
    result += a[i][j]*b[j][k];
  return result;
}
```

Dynamic Nested Arrays

Strength

- Can create matrix of arbitrary size

Programming

- Must do index computation explicitly

Performance

- Accessing single element costly
- Must do multiplication

```
int * new_var_matrix
  (long int n)
{
  return (int *)
    calloc(sizeof(int), n*n);
}
```

```
int var_ele
  (int *a, long int i,
   long int j, long int n)
{
  return a[i*n+j];
}
```

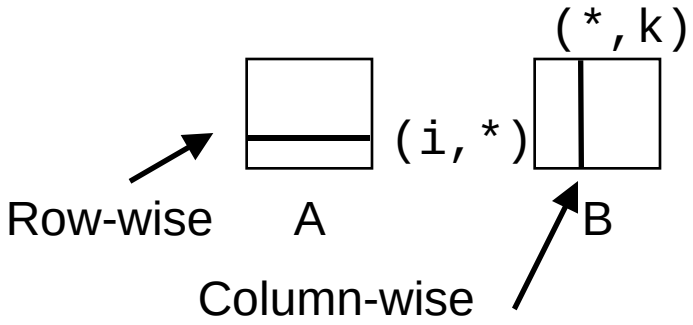
```
var_ele..ng:
 mulq $17,$19,$19   # i*n
 addq $19,$18,$19   # i*n+j
 s4addq $19,$16,$19 # a+i*n+j
 ldl $0,0($19)      # Get element
 ret $31,($26),1
```

Dynamic Array Multiplication

Without Optimizations

- **Multiplies**
  - 2 for subscripts
  - 1 for data
- **Adds**
  - 4 for array indexing
  - 1 for loop index
  - 1 for data

```
/* Compute element i,k of
   variable matrix product */
int var_prod_ele
(int *a, int *b,
 long int i, long int k,
 long int n)
{
  long int j;
  int result = 0;
  for (j = 0; j < n; j++)
    result +=
      a[i*n+j] * b[j*n+k];
  return result;
}
```



Optimizing Dynamic Array Multiplication

Optimizations

- Performed when set optimization level to `-O2`

Code Motion

- Expression `i*n` can be computed outside loop

Strength Reduction

- Incrementing `j` has effect of incrementing `j*n+k` by `n`

Performance

- Compiler can optimize regular access patterns

```
{
  long int j;
  int result = 0;
  for (j = 0; j < n; j++)
    result +=
      a[i*n+j] * b[j*n+k];
  return result;
}
```

```
{
  long int j;
  int result = 0;
  long int iTn = i*n;
  long int jTnPk = k;
  for (j = 0; j < n; j++) {
    result +=
      a[iTn+j] * b[jTnPk];
    jTnPk += n;
  }
  return result;
}
```

Dynamic Array Multiplication

Optimized Code

```
{
  long int j;
  int result = 0;
  long int iTn = i*n;
  long int jTnPk = k;
  for (j = 0; j < n; j++) {
    result +=
      a[iTn+j] * b[jTnPk];
    jTnPk += n;
  }
  return result;
}
```

Inner Loop

```
  # $0:  result
  # $4:  j
  # $18: i*n
  # $19: j*n+k (Initially =k)
$46:                    # Loop
  addq $18,$4,$1        # i*n+j
  s4addq $1,$16,$1      # &a[i][j]
  s4addq $19,$17,$2     # &b[j][k]
  ldl $3,0($1)          # a[i][j]
  ldl $1,0($2)          # b[j][k]
  mull $3,$1,$3         # product
  addq $4,1,$4          # j++
  addq $19,$20,$19      # $19+= n
  cmplt $4,$20,$1       # j < n?
  addl $0,$3,$0         # result+= ..
  bne $1,$46            # goto Loop
```
