## Lecture 18 <br> List Scheduling \& Global Scheduling

Reading: Chapter 10.3-10.4

## Review: The Ideal Scheduling Outcome

- What prevents us from achieving this ideal?

## Review: Scheduling Constraints

- Hardware Resources
- finite set of FUs with instruction type, bandwidth, and latency constraints
- cache hierarchy also has many constraints
- Data Dependences
- can't consume a result before it is produced
- ambiguous dependences create many challenges
- Control Dependences
- impractical to schedule for all possible paths
- choosing an "expected" path may be difficult
- recovery costs can be non-trivial if you are wrong

## Scheduling Roadmap

List Scheduling:

- within a basic block

Global Scheduling:

- across basic blocks

Software Pipelining: - across loop iterations

## List Scheduling

- The most common technique for scheduling instructions within a basic block

We don't need to worry about:

- control flow

We do need to worry about:

- data dependences
- hardware resources

- Even without control flow, the problem is still NP-hard

## List Scheduling Algorithm: Inputs and Outputs

Algorithm reproduced from:

- "An Experimental Evaluation of List Scheduling", Keith D. Cooper, Philip J. Schielke, and Devika Subramanian. Rice University, Department of Computer Science Technical Report 98-326, September 1998.

Inputs:

Machine Parameters

```
# of FUs:
    2 INT, 1 FP
Latencies:
    add = 1 cycle, ...
Pipelining:
    1 add/cycle, ...
```

## Output:

Scheduled Code Cycle

| I0 | I2 | --- | 0 |
| :--- | :--- | :--- | :--- |
| --- | I1 | I4 | 1 <br> I3 <br> I8 |
| I6 | 2 |  |  |
| I10 | --- | I11 | 3 |
| I7 | I9 | I5 | 4 |
| 4 |  |  |  |

## List Scheduling: The Basic Idea

- Maintain a list of instructions that are ready to execute
- data dependence constraints would be preserved
- machine resources are available
- Moving cycle-by-cycle through the schedule template:
- choose instructions from the list \& schedule them
- update the list for the next cycle

Cycle

## What Makes Life Interesting: Choice

## Easy case:

- all ready instructions can be scheduled this cycle

Interesting case:

- we need to pick a subset of the ready instructions

- List scheduling makes choices based upon priorities
- assigning priorities correctly is a key challenge

## Intuition Behind Priorities

- Intuitively, what should the priority correspond to?
- What factors are used to compute it?
- data dependences?
- machine parameters?

```
# of FUs:
    2 INT, 1 FP
    Latencies:
    add = 1 cycle, ...
Pipelining:
    1 add/cycle, ...
```

## Representing Data Dependences: <br> The Data Precedence Graph (DPG)

- Two different kinds of edges:

Code
DPG

- What about output dependences?

## Computing Priorities

- Let's start with just true dependences (i.e. "edges" in DPG)
- Priority = latency-weighted depth in the DPG

$$
\operatorname{priority}(x)=\max \left(\forall_{l \in \text { leaves }(D P G)} \forall_{p \in \operatorname{paths}(x, \ldots, l)} \sum_{p_{i}=x}^{l} \operatorname{latency}\left(p_{i}\right)\right)
$$

## Computing Priorities (Cont.)

- Now let's also take anti-dependences into account
- i.e. anti-edges in the set $E^{\prime}$

$$
\operatorname{priority}(x)= \begin{cases}\operatorname{latency}(x) & \text { if } x \text { is a leaf } \\ {\max \left(\operatorname{latency}(x)+\max _{(x, y) \in E}(\operatorname{priority}(y)),\right.} \quad \\ \left.\max _{(x, y) \in E^{\prime}}(\operatorname{priority}(y))\right) & \text { otherwise } .\end{cases}
$$

## List Scheduling Algorithm

```
cycle = 0;
ready-list = root nodes in DPG; inflight-list = {};
while ((|ready-list|+|inflight-list| > 0) && an issue slot is available) {
    for op = (all nodes in ready-list in descending priority order) {
        if (an FU exists for op to start at cycle) {
            remove op from ready-list and add to inflight-list;
            add op to schedule at time cycle;
            if (op has an outgoing anti-edge)
                add all targets of op's anti-edges that are ready to ready-list;
        }
    }
    cycle = cycle + 1;
    for op = (all nodes in inflight-list)
        if (op finishes at time cycle) {
            remove op from inflight-list;
            check nodes waiting for op & add to ready-list if all operands
    available;
        }
    }
}
```

## Example

$$
\begin{aligned}
& \text { I0: } \mathrm{a}=1 \\
& \text { I1: } \mathrm{f}=\mathrm{a}+\mathrm{x} \\
& \text { I2: } \mathrm{b}=7 \\
& \text { I3: } \mathrm{c}=9 \\
& \text { I4: } \mathrm{g}=\mathrm{f}+\mathrm{b} \\
& \text { I5: } \mathrm{d}=13 \\
& \text { I6: } \mathrm{e}=19 ; \\
& \text { I7: } \mathrm{h}=\mathrm{f}+\mathrm{c} \\
& \text { I8: } \mathrm{j}=\mathrm{d}+\mathrm{y} \\
& \text { I9: } \mathrm{z}=-1 \\
& \text { I10: JMP L1 }
\end{aligned}
$$

- 2 identical fully-pipelined FUs
- adds take 2 cycles; all other insts take 1 cycle

## Example

$$
\begin{aligned}
& \text { I0: } \mathrm{a}=1 \\
& \text { I1: } \mathrm{f}=\mathrm{a}+\mathrm{x} \\
& \text { I2: } \mathrm{b}=7 \\
& \text { I3: } \mathrm{c}=9 \\
& \text { I4: } \mathrm{g}=\mathrm{f}+\mathrm{b} \\
& \text { I5: } \mathrm{d}=13 \\
& \text { I6: } \mathrm{e}=19 ; \\
& \text { I7: } \mathrm{h}=\mathrm{f}+\mathrm{c} \\
& \text { I8: } \mathrm{j}=\mathrm{d}+\mathrm{y} \\
& \text { I9: } \mathrm{z}=-1 \\
& \text { I10: JMP L1 }
\end{aligned}
$$

- 2 identical fully-pipelined FUs
- adds take 2 cycles; all other insts take 1 cycle

## What if We Break Ties Differently?

```
IO: a = 1
I1: f = a + x
I2: b = 7
I3: c = 9
I4: g=f+b
I5: d = 13
I6: e = 19;
I7: h = f + c
I8: j = d + y
I9: z = -1
I10: JMP L1
```

Cycle

- 2 identical fully-pipelined FUs
- adds take 2 cycles; all other insts take 1 cycle

## What if We Break Ties Differently?

```
IO: a = 1
I1: f = a + x
I2: b = 7
I3:c=9
I4: g=f+b
I5: d = 13
I6: e = 19;
I7: h = f + c
I8: j = d + y
I9: z = -1
I10: JMP L1
```

Cycle

| IO | I2 |
| :---: | :---: |
| I1 | I5 |
| I3 | ) |
| I4 | I7 |
| I9 | I6 |
| I10 |  |
|  |  |

- 2 identical fully-pipelined FUs
- adds take 2 cycles; all other insts take 1 cycle

## Contrasting the Two Schedules

- Breaking ties arbitrarily may not be the best approach

## Backward List Scheduling

Modify the algorithm as follows:

- reverse the direction of all edges in the DPG
- schedule the finish times of each operation
- start times must still be used to ensure FU availability

Impact of scheduling backwards:

- clusters operations near the end (vs. the beginning)
- may be either better or worse than forward scheduling

## Backward List Scheduling Example: Let's Schedule it Forward First

Hardware parameters:

| INT | INT | MEM | Cycle |
| :---: | :---: | :---: | :---: |
| LDIa | LSL | ---- | 0 |
| LDIb | LDIc | ---- | 1 |
| LDId | ADDa | ---- | 2 |
| ADDb | ADDC | ---- | 3 |
| ADDd | ADDI | STa | 4 |
| CMP | ---- | STb | 5 |
| ---- | ---- | STc | 6 |
| - | ---- | STd | 7 |
| ---- | ---- | STe | 8 |
| ---- | ---- | ---- | 9 |
| ---- | ---- | ---- | 10 |
| ---- | ---- | ---- | 11 |
| BR | ---- | ---- | 12 |

- 2 INT units: ADDs take 2 cycles; others take 1 cycle
- 1 MEM unit: stores (ST) take 4 cycles

## Now Let's Try Scheduling Backward

| INT | INT | MEM | Cycle |
| :---: | :---: | :---: | :---: |
| LDIa | ---- | -- | 0 |
| ADDI | LSL | ---- | 1 |
| ADDd | LDIc | ---- | 2 |
| ADDC | LDId | STe | 3 |
| ADDb | LDIa | STd | 4 |
| ADDa | -- | STc | 5 |
| -- | ---- | STb | 6 |
| ---- | ---- | STa | 7 |
| ---- | ---- | ---- | 8 |
| ---- | ---- | ---- | 9 |
| CMP | ---- | ---- | 10 |
| BR | ---- | ---- | 11 |

Hardware parameters:

- 2 INT units: ADDs take 2 cycles; others take 1 cycle
- 1 MEM unit: stores (ST) take 4 cycles

## Contrasting Forward vs. Backward List Scheduling

Forward

| INT | INT | MEM | Cycle |
| :---: | :---: | :---: | :---: |
| LDIa | LSL | ---- | 0 |
| LDIb | LDIc | ---- | 1 |
| LDId | ADDa | ---- | 2 |
| ADDb | ADDC | ---- | 3 |
| ADDd | ADDI | STa | 4 |
| CMP | ---- | STb | 5 |
| ---- | ---- | STC | 6 |
| ---- | ---- | STd | 7 |
| ---- | ---- | STe | 8 |
| -- | ---- | --- | 9 |
| ---- | ---- | ---- | 10 |
| ---- | --- | --- | 11 |
| BR | ---- | ---- | 12 |

Backward

| INT | INT | MEM | Cycle |
| :---: | :---: | :---: | :---: |
| LDIa | ---- | ---- | 0 |
| ADDI | LSL | ---- | 1 |
| ADDd | LDIc | ---- | 2 |
| ADDC | LDId | STe | 3 |
| ADDb | LDIa | STd | 4 |
| ADDa | ---- | STC | 5 |
| ---- | ---- | STb | 6 |
| ---- | ---- | STa | 7 |
| -- | ---- | ---- | 8 |
| ---- | ---- | ---- | 9 |
| CMP | ---- | ---- | 10 |
| BR | ---- | --- | 11 |

- backward scheduling clusters work near the end
- backward is better in this case, but this is not always true

## Evaluation of List Scheduling

Cooper et al. propose "RBF" scheduling:

- schedule each block $M$ times forward \& backward
- break any priority ties randomly

For real programs:

- regular list scheduling works very well

For synthetic blocks:

- RBF wins when "available parallelism" (AP) is ~2.5
- for smaller AP, scheduling is too constrained
- for larger AP, any decision tends to work well

## List Scheduling Wrap-Up

- The priority function can be arbitrarily sophisticated
- e.g., filling branch delay slots in early RISC processors
- List scheduling is widely used, and it works fairly well
- It is limited, however, by basic block boundaries

## Scheduling Roadmap

List Scheduling:

- within a basic block

Global Scheduling:

- across basic blocks

Software Pipelining: - across loop iterations

## Introduction to Global Scheduling

Assume each clock can execute 2 operations of any kind.

## Result of Code Scheduling

## Terminology

## Control equivalence:

- Two operations $\mathrm{o}_{1}$ and $\mathrm{o}_{2}$ are control equivalent if $o_{1}$ is executed if and only if $o_{2}$ is executed.

## Control dependence:

- An op $\mathrm{o}_{2}$ is control dependent on op $\mathrm{o}_{1}$ if the execution of $\mathrm{o}_{2}$ depends on the outcome of $o_{1}$.

## Speculation:

- An operation o is speculatively executed if it is executed before all the operations it depends on (control-wise) have been executed.
- Requirements:
- does not raise an exception
- satisfies data dependences

## Code Motions

Goal: Shorten execution time probabilistically

Moving instructions up:

- Move instruction to a cut set (from entry)
- Speculation: even when not anticipated.

Moving instructions down:

- Move instruction to a cut set (from exit)
- May execute extra instruction
- Can duplicate code

## A Note on Data Dependences

## General-Purpose Applications

- Lots of data dependences
- Key performance factor: memory latencies
- Move memory fetches up
- Speculative memory fetches can be expensive
- Control-intensive: get execution profile
- Static estimation
- Innermost loops are frequently executed
- back edges are likely to be taken
- Edges that branch to exit and exception routines are not likely to be taken
- Dynamic profiling
- Instrument code and measure using representative data

## A Basic Global Scheduling Algorithm

- Schedule innermost loops first
- Only upward code motion
- No creation of copies
- Only one level of speculation

## Program Representation

- A region in a control flow graph is:
- a set of basic blocks and all the edges connecting these blocks,
- such that control from outside the region must enter through a single entry block.
- A procedure is represented as a hierarchy of regions
- The whole control flow graph is a region
- Each natural loop in the flow graph is a region
- Natural loops are hierarchically nested
- Schedule regions from inner to outer
- treat inner loop as a black box unit
- can schedule around it but not into it
- ignore all the loop back edges $\rightarrow$ get an acyclic graph

## Algorithm

```
Compute data dependences;
For each region from inner to outer {
    For each basic block B in prioritized topological order {
    CandBlocks = ControlEquiv{B} U
                    Dominated-Successors{ControlEquiv{B}};
    CandInsts = ready operations in CandBlocks;
    For ( }\dagger=0,1,\ldots.\mathrm{ until all operations from B are scheduled) {
            For ( }n\mathrm{ in CandInst in priority order) {
            if ( }n\mathrm{ has no resource conflicts at time t) {
                S(n)=< B, t>
                Update resource commitments
                Update data dependences
            }
        }
        Update CandInsts:
    }}}
```

Priority functions: non-speculative before speculative

## Extensions

- Prepass before scheduling: loop unrolling
- Especially important to move operation up loop back edges

## Summary

- Global scheduling
- Legal code motions
- Heuristics
