1. Introduction

The question of whether branching-time temporal logic or linear-time temporal logic is best for reasoning about concurrent programs is one of the most controversial issues in logics of programs. Concurrent programs are usually modelled by labelled state-transition graphs in which some state is designated as the initial state. For historical reasons such graphs are called Kripke structures [8]. In linear temporal logic, operators are provided for describing events along a single time path (i.e., along a single path in a Kripke structure). In a branching-time logic the temporal operators quantify over the futures that are possible from a given state (i.e., over the possible paths that lead from a state). It is well known that the two types of temporal logic have different expressive powers ([4], [9]). Linear temporal logic, for example, can express certain fairness properties that cannot be expressed in branching-time temporal logic. On the other hand, certain practical decision problems like model checking ([3], [16]) are easier for branching-time temporal logic than for linear temporal logic.

In this paper we provide further insight on which type of logic is best. We show that if two finite Kripke structures can be distinguished by some formula that contains both branching-time and linear-time operators, then the structures can be distinguished by a formula that contains only branching-time operators. Specifically, we show that if two finite Kripke structures can be distinguished by some formula of the logic CTL* (i.e., if there is some CTL* formula that is true in one but not in the other), then they can be distinguished by some formula of the logic CTL. The logic CTL* ([3], [4]) is a very powerful temporal logic that combines both branching-time and linear-time operators; a path quantifier, either A ("for all paths") or E ("for some paths") can prefix an assertion composed of arbitrary combinations of the usual linear time operators G ("always"), F ("sometimes"), X ("nexttime"), and U ("until"). CTL ([1], [2]) is a restricted subset of CTL* that permits only branching-time operators—each path quantifier must be immediately followed by exactly one of the operators G, F, X, or U.

Our goal is to show that for any finite Kripke structure M, it is possible to construct a CTL formula $F_M$ that
uniquely characterizes $M$. Since one Kripke structure may be a trivial unrolling of another, we use a notion of equivalence between Kripke structures that is similar to the notion of bisimulation studied by Milner [12]. We say that states $s$ and $s'$ are equivalent if they have the same labelling of atomic propositions and for each transition from one of the two states to some state $t$ there is a corresponding transition from the other state to a state $t'$ that is equivalent to $t$. Two Kripke structures are equivalent if their initial states are equivalent. It is not difficult to prove that if two Kripke structures are equivalent, then their initial states must satisfy the same $\text{CTL}^*$.

An obvious first attempt to construct $F_M$ is simply to write a $\text{CTL}$ formula that specifies the transition relation of $M$. For each state $s$ in $M$ we include in $F_M$ a conjunct of the form

$$\text{AG}(L(s) \Rightarrow \bigwedge_i \text{EX}L(s_i) \land \text{AX}(\bigvee_i L(s_i)))$$

where $s_1, \ldots, s_n$ are the successors of $s$ and $L(t)$ is the labelling of atomic propositions associated with state $t$. It is easy to see, however, that this simple approach cannot work in general: several states in $M$ may have exactly the same labelling of atomic propositions.

Instead, we first show that it is possible to write a $\text{CTL}$ formula that will distinguish between two states in the same structure that are not equivalent according to the above definition. Two inequivalent states may have exactly the same labelling of atomic propositions, they may even have corresponding successors, but the computation trees rooted at those states must differ at some finite depth. The difference in the computation trees can be exploited to give a $\text{CTL}$ formula that distinguishes between the states. Since equivalent states satisfy the same $\text{CTL}^*$ formulas, it follows that if two states can be distinguished by a $\text{CTL}^*$ formula, they can be distinguished by a $\text{CTL}$ formula. Once we can distinguish between inequivalent states in the same structure, we can write a single $\text{CTL}$ formula that encodes the entire Kripke structure; this formula is the $F_M$ that we seek.

The above construction requires the use of the nexttime operator in specifying $F_M$. In reasoning about concurrent systems, however, the nexttime operator may be dangerous, since it refers to the global next state instead of the local next state within a process [10]. What happens if we disallow the nexttime operator in CTL formulas? The proof, in this case, requires another notion of equivalence—equivalence with respect to stuttering. We say that two state sequences correspond if each can be partitioned into finite blocks of identically labelled states such that each state in the $i$-th block in one sequence is equivalent to each state in the $i$-th block of the other sequence. Thus, duplicating some state in a sequence any finite number of times will always result in a corresponding sequence. We say that two states are equivalent if for each state sequence starting at one there is a corresponding state sequence that starts at the other. Under this second notion of equivalence the proof of the characterization theorem becomes much more complicated, since it is possible
for two inequivalent states to have exactly the same finite behaviors (modulo stuttering), but different infinite behaviors.

Equivalence under stuttering turns out to be quite useful for reasoning about hierarchically constructed concurrent systems. In determining the correctness of such a system by using a technique like temporal logic model checking ([2], [3], [11], [13], [16], [17]), it is often desirable to replace a low level module by an equivalent structure with fewer states. Our results show how this can be done while preserving all of those properties that are invariant under stuttering. We give polynomial algorithms both for determining if two structures are equivalent with respect to stuttering and for minimizing the number of states in a given structure under this notion of equivalence.

Finally, our results have some interesting implications for the problem of synthesizing finite state concurrent systems from temporal logic specifications ([2], [14]). In order to guarantee that any Kripke structure can be synthesized from a specification in linear temporal logic, Wolper [18] was forced to introduce more complicated operators based on regular expressions. Our results show that (at least in theory) no such extension is necessary for branching-time temporal logic. Any Kripke structure can be specified directly by a formula of branching-time logic.

The expressive power of various temporal logics has been discussed in several papers; see ([4], [9]) for example. Hennessy and Milner [7], Graf and Sifakis [6], and Pnueli [15] have all discussed the relationship between temporal logic and various notions of equivalence between models of concurrent programs. However, we believe that we are the first to show that it is possible to characterize Kripke models within branching-time logic and to investigate the consequences of this result.

Our paper is organized as follows: In Section 2 we describe the logics CTL and CTL*. In Section 3, we state formally what it means for two states in a Kripke structure to be equivalent and prove that equivalent states satisfy exactly the same CTL* formulas. Section 3 also contains the first of the two main results of the paper: we show how to characterize Kripke structures using CTL formulas with the nexttime operator. Section 4 introduces the second notion of equivalence (equivalence with respect to stuttering) and shows that if the nexttime operator is disallowed, then equivalent states again satisfy exactly the same CTL* formulas. We also extend the characterization theorem of Section 3 to Kripke structures with the new notion of equivalence. In Section 5 we give a polynomial algorithm for determining if two states are equivalent up to stuttering. The paper concludes in Section 6 with a discussion of some remaining open problems like the possibility of extending our results to Kripke structures with fairness constraints (i.e., Büchi Automata).
2. The Logics CTL and CTL$^*$

There are two types of formulas in CTL$^*$: state formulas (which are true in a specific state) and path formulas (which are true along a specific path). Let AP be the set of atomic proposition names. A state formula is either:

- $A$, if $A \in AP$.
- If $f$ and $g$ are state formulas, then $\neg f$ and $f \lor g$ are state formulas.
- If $f$ is a path formula, then $E(f)$ is a state formula.

A path formula is either:

- A state formula.
- If $f$ and $g$ are path formulas, then $\neg f$, $f \lor g$, $Xf$, and $f U g$ are path formulas.

CTL$^*$ is the set of state formulas generated by the above rules.

CTL is a subset of CTL$^*$ in which we restrict the path formulas to be:

- If $f$ and $g$ are state formulas, then $X f$ and $f U g$ are path formulas.
- If $f$ is a path formula, then so is $\neg f$.

We define the semantics of both logics with respect to a structure $M = \langle S, R, L \rangle$, where

- $S$ is a set of states.
- $R \subseteq S \times S$ is the transition relation, which must be total. We write $s_i \rightarrow s_j$ to indicate that $(s_i, s_j) \in R$.
- $L : S \rightarrow \mathcal{P}(AP)$ is the proposition labeling.

Unless otherwise stated, all of our results apply only to finite Kripke structures.

We only consider transition relations where every state is reachable from the initial state. We define a path in $M$ to be a sequence of states, $\pi = s_0, s_1, \ldots$ such that for every $i \geq 0$, $s_i \rightarrow s_{i+1}$. $\pi^i$ will denote the suffix of $\pi$ starting at $s_i$.

We use the standard notation to indicate that a state formula $f$ holds in a structure: $M, s \models f$ means that $f$ holds at state $s$ in structure $M$. Similarly, if $f$ is a path formula, $M, \pi \models f$ means that $f$ holds along path $\pi$ in structure $M$. The relation $\models$ is defined inductively as follows (assuming that $f_1$ and $f_2$ are state formulas and $g_1$ and $g_2$ are path formulas):

1. $s \models A \iff A \in L(s)$.
2. $s \models \neg f_1 \iff s \not\models f_1$.
3. $s \models f_1 \lor f_2 \iff s \models f_1$ or $s \models f_2$. 
4. \( s \models E(g_i) \iff \) there exists a path \( \pi \) starting with \( s \) such that \( \pi \models g_i \).

5. \( \pi \models f_i \iff s \) is the first state of \( \pi \) and \( s \models f_i \).

6. \( \pi \models \neg g_i \iff \pi \not\models g_i \).

7. \( \pi \models g_i \lor g_j \iff \pi \models g_i \) or \( \pi \models g_j \).

8. \( \pi \models Xg_i \iff \pi^1 \models g_i \).

9. \( \pi \models g_i U g_j \iff \) there exists a \( k \geq 0 \) such that \( \pi^k \models g_j \) and for all \( 0 \leq j < k \), \( \pi^j \not\models g_i \).

We will also use the following abbreviations in writing CTL* (and CTL) formulas:

- \( f \land g \equiv \neg (\neg f \lor \neg g) \)
- \( Ff \equiv \text{true} \cup f \)
- \( \Lambda(f) \equiv \neg E(\neg f) \)
- \( Gf \equiv \neg F\neg f. \)

3. Equivalence of Kripke Structures

Given two structures \( M \) and \( M' \) with the same set of atomic propositions \( AP \), we define a sequence of equivalence relations \( E_0, E_1, \ldots \) on \( S \times S' \) as follows:

- \( s E_0 s' \) if and only if \( L(s) = L(s') \).
- \( s E_{n+1} s' \) if and only if
  - \( L(s) = L(s') \).
  - \( \forall s_i [s \rightarrow s_i = \exists s_i'[s' \rightarrow s_i' \land s_i E_{n} s_i'] \land \]
  - \( \forall s_i'[s' \rightarrow s_i' = \exists s_i[s \rightarrow s_i \land s_i E_{n} s_i'] \].

Now, we define our notion of equivalence between states: \( s E s' \) if and only if \( s E_i s' \) for all \( i \geq 0 \). Furthermore, we say that \( M \) with initial state \( s_0 \) is equivalent to \( M' \) with initial state \( s'_0 \) iff \( s_0 E s'_0 \).

Lemma 1: Let \( s E s' \), then for every path, \( s, s', \ldots \), there exists a path, \( s', s'_1, \ldots \) such that \( \forall i [s_i E s'_i] \).

Proof: Note first that \( E_{n+1} \subseteq E_n \). Since \( E_0 \) is finite, there must be a \( k \) such that \( E_{k+1} = E_k = E \). Thus, we can substitute \( E \) for \( E_k \) in the definition of \( E_{k+1} \) giving \( s E s' \) if and only if

- \( L(s) = L(s') \).
- \( \forall s_i [s \rightarrow s_i = \exists s_i'[s' \rightarrow s_i' \land s_i E_{n} s_i'] \land \]
- \( \forall s_i'[s' \rightarrow s_i' = \exists s_i[s \rightarrow s_i \land s_i E_{n} s_i'] \].

The remainder of the proof is a straightforward induction on the length of the path. \( \square \)
Theorem 2: If $s \models s'$, then $\forall f \in \mathcal{L} \cdot [s \models f \Rightarrow s' \models f]$.

This theorem is a consequence of the following lemma:

Lemma 3: Let $h$ be either a state formula or a path formula. Let $s = s_1, \ldots$ be a path in $M$ and $\pi' = s', s'_1, \ldots$ be a path in $M'$ such that $s \models s'$ and $\forall f [s \models E s']$. Then

$s \models h \Rightarrow s' \models h$, if $h$ is a state formula and

$\pi \models h \Rightarrow \pi' \models h$, if $h$ is a path formula.

Proof: We prove the theorem by induction on the structure of $h$.

Base: $h = A$. By the definition of $E$, $s \models A \Rightarrow s' \models A$.

Induction: There are several cases.

1. $h = \lnot h_1$, a state formula.

$s \models h \Rightarrow s \not\models h_1$

$\Rightarrow s' \not\models h_1$ (induction hypothesis)

$\Rightarrow s' \models h$

The same reasoning holds if $h$ is a path formula.

2. $h = h_1 \lor h_2$, a state formula.

Without loss of generality,

$s \models h \Rightarrow s \models h_1$ or $s \models h_2$

$\Rightarrow s \models h_1$

$\Rightarrow s' \models h_1$ (induction hypothesis)

$\Rightarrow s' \models h$

The argument is the same in the other direction. We can also use this argument if $h$ is a path formula.

3. $h = E(h_1)$, a state formula.

Suppose that $s \models h$. Then there is a path, $\pi_1$, starting with $s$ such that $\pi_1 \models h_1$. By Lemma 1, there is a corresponding path $\pi'_1$ in $M'$ starting with $s'$. So by the induction hypothesis, $\pi_1 \models h_1 \Rightarrow \pi'_1 \models h_1$. Therefore, $s \models E(h_1) \Rightarrow s' \models E(h_1)$. We can use the same argument in the other direction, so the lemma holds.
4. \( h = h_1 \), where \( h \) is a path formula and \( h_1 \) is a state formula.

Although the lengths of \( h \) and \( h_1 \) are the same, we can imagine that \( h = \text{path}(h_1) \), where path is an operator which converts a state formula into a path formula. Therefore, we are simplifying \( h \) by dropping this path operator. So now:

\[
\pi \models h \iff s \models h_1 \\
\iff s' \models h_1 \text{ (induction hypothesis)} \\
\implies \pi' \models h.
\]

The reverse direction is similar.

5. \( i = X h_1 \), a path formula.

By the definition of the next-time operator, \( \pi^1 \models h_1 \). Since \( \pi \) and \( \pi' \) correspond, so do \( \pi^1 \) and \( \pi'^1 \). Therefore, by the inductive hypothesis, \( \pi'^1 \models h_1 \) so \( \pi' \models h \).

We can use the same argument in the other direction.

6. \( h = h_1 \cup h_2 \), a path formula.

Suppose that \( \pi \models h_1 \cup h_2 \). By the definition of the until operator, there is a \( k \) such that \( \pi^k \models h_2 \) and for all \( 0 \leq j < k \), \( \pi'^j \models h_1 \). Since \( \pi \) and \( \pi' \) correspond, so do \( \pi^j \) and \( \pi'^j \) for any \( j \). Therefore, by the inductive hypothesis, \( \pi'^k \models h_2 \) and \( \pi'^j \models h_1 \) for all \( 0 \leq j < k \). Therefore \( \pi' \models h \).

We can use the same argument in the other direction. \( \square \)

Another property of two equivalent states is that they both have corresponding computation trees. For every \( s \in S \), \( \text{Tr}_n(s) \) is the computation tree of depth \( n \) rooted at \( s \). Formally, \( \text{Tr}_n(s) \) consists of a single node which has the same label as \( s \). \( \text{Tr}_{n+1}(s) \) has as its root a node \( m \) with the same label as \( s \). If \( s \) has successors \( s_1, \ldots, s_p \) in the Kripke structure, then node \( m \) will have subtrees \( \text{Tr}_n(s_1), \ldots, \text{Tr}_n(s_p) \).

Two trees \( \text{Tr}_n(s) \) and \( \text{Tr}_n(s') \) correspond (denoted \( \text{Tr}_n(s) \equiv \text{Tr}_n(s') \)) if and only if both of their roots have the same label and for every subtree of depth \( n-1 \) of the root of one, it is possible to find a corresponding subtree of the root of the other.

Lemma 4: \( s \models s' \) if and only if \( \text{Tr}_j(s) \equiv \text{Tr}_j(s') \) for all \( j \leq n \).
Lemma 5: Given a finite set of states $s_1, \ldots, s_n$ there exists a $c$ such that if two states $s_i$ and $s_j$ are not $E$-equivalent then $\text{Tr}_c(s_i)$ and $\text{Tr}_c(s_j)$ will not correspond.

We will call the value of $c$ for $S$ the characteristic number of the structure.

We associate a CTL formula with a tree $\text{Tr}_n(s)$ as follows:

- $\mathcal{G}[\text{Tr}_n(s)] = (p_1 \land \ldots \land p_u) \land (\neg q_1 \land \ldots \land \neg q_v)$, where $L(s) = \{ p_1, \ldots, p_u \}$ and $AP - L(s) = \{ q_1, \ldots, q_v \}$.
- $\mathcal{G}[\text{Tr}_{n+1}(s)] = (\land \mathcal{E} \mathcal{G}[\text{Tr}_n(s)]) \land \mathcal{A} \mathcal{X} (\lor \mathcal{G}[\text{Tr}_n(s)]) \land \mathcal{G}[\text{Tr}_n(s)]$, where $s_i$ is a successor of $s$.

Lemma 6: $s \models \mathcal{G}[\text{Tr}_n(s)]$ for all $n \geq 0$.

Lemma 7: If $s \models \mathcal{G}[\text{Tr}_n(s')]$, then $\text{Tr}_n(s) \equiv \text{Tr}_n(s')$.

Proof: The proof is by induction on $n$. The basis case is trivial. Thus, we assume that $n > 0$. Let $s_1, s_2, \ldots, s_p$ be the sons of $s$ in $\text{Tr}_n(s)$ and $s'_1, s'_2, \ldots, s'_q$ be the sons of $s'$ in $\text{Tr}_n(s')$.

It is easy to see that $s$ and $s'$ have the same labelling of atomic propositions.

We must show that $\text{Tr}_{n-1}(s'_0)$ corresponds to some $\text{Tr}_{n-1}(s'_j)$. Since $s \models \mathcal{G}[\text{Tr}_n(s')]$, $s \models \mathcal{A} \mathcal{X} (\lor \mathcal{G}[\text{Tr}_{n-1}(s'_j)])$. Since $s'_0$ is a successor of $s$, $s'_0 \models \mathcal{G}[\text{Tr}_{n-1}(s'_j)]$ for some $j$. Hence, $\text{Tr}_{n-1}(s'_0) \equiv \text{Tr}_{n-1}(s'_j)$ by our inductive hypothesis.

Finally, we must show that $\text{Tr}_{n-1}(s'_0)$ corresponds to some $\text{Tr}_{n-1}(s)$. Since $s \models \mathcal{G}[\text{Tr}_n(s')]$, $s' \models \mathcal{E} \mathcal{G}[\text{Tr}_{n-1}(s'_j)]$. Since $s'_0$ is a successor of $s'$, $s' \models \mathcal{E} \mathcal{G}[\text{Tr}_{n-1}(s'_j)]$. Therefore, there exists an $i$ such that $s'_i \models \mathcal{G}[\text{Tr}_{n-1}(s'_0)]$. Hence, $\text{Tr}_{n-1}(s'_i) \equiv \text{Tr}_{n-1}(s'_0)$ by our inductive hypothesis. \qed

Lemma 8: If $s$ is a state in a Kripke structure $M$, then there is a CTL formula, $C(M,s)$ that determines $s$ up to $E$-equivalence within $M$, i.e. $C(M,s)$ is true in $s$ and every state in $M$ that is $E$-equivalent to $s$ but false in every state in $M$ that is not equivalent to $s$.

Proof: We choose $C(M,s) = \mathcal{G}[\text{Tr}_c(s)]$ where $c$ is the characteristic number of $M$. $C(M,s)$ is true in $s$ and hence in all states $E$-equivalent to $s$. Let $s'$ be a state that is not $E$-equivalent to $s'$; then $\text{Tr}_c(s) \not\equiv \text{Tr}_c(s')$. Hence, by lemma 7, $s' \not\models C(M,s)$. \qed

Theorem 9: Given a Kripke structure $M$ with initial state $s_0$, there is a CTL formula $F(M,s_0)$ that characterizes that structure up to $E$-equivalence, i.e. $M', s'_0 \models F(M,s_0) \iff s_0 E s'_0$. 

Proof: For any state s in M, let s₁, ..., sₚ be the successors of s. We define

\[ G(M,s) = AG(C(M,s) \land \bigwedge_i C(M,s_i) \land AX \bigvee_i C(M,s_i)) \]

\[ G(M,s) \] describes all of the possible transitions from s. \( F(M,s_0) \) is the formula \( C(M,s_0) \land \bigwedge_s G(M,s) \). If two structures \( M,s_0 \) and \( M',s'_0 \) are equivalent then by theorem 2 they satisfy the same formulas. Since \( M,s_0 \models F(M,s_0) \), so does \( M',s'_0 \).

For the other direction we show by induction on \( n \) that if \( M',s'_0 \models F(M,s_0) \) then \( Tr_n(s_0) \equiv Tr_n(s'_0) \) for all \( n \geq 0 \). By lemma 4, the two structures are then \( E \)-equivalent. □

Corollary 10: Given two structures \( M \) and \( M' \) with initial states \( s_0 \) and \( s'_0 \) respectively, \( s_0 E s'_0 \) if and only if \( \forall f \in CTL^+ [M,s_0 \models f = M',s'_0 \models f] \).

Corollary 11: Given two structures \( M \) and \( M' \) with initial states \( s_0 \) and \( s'_0 \) respectively, if there is a formula of \( CTL^+ \) that is true in one and false in the other, then there is also a formula of \( CTL \) that is true in the one and false in the other.

We illustrate our method of characterizing Kripke structures with the example in figure 3-1.

---

**Figure 3-1:** A Kripke structure in which every other state is labelled A

The characteristic number of this structure is 1, since \( Tr_0(s_0) \not\equiv Tr_0(s_1) \), \( Tr_0(s_0) \not\equiv Tr_0(s_2) \), and \( Tr_1(s_0) \not\equiv Tr_1(s_1) \). Let

- \( C(M,s_0) = a \land \neg b \land EX(a \land \neg b) \land EX(\neg a \land b) \land AX(a \land \neg b) \lor \neg a \land b) \)

- \( C(M,s_1) = a \land \neg b \land EX(a \land \neg b) \land AX(a \land \neg b) \land EX(a \land \neg b) \land AX(a \land \neg b) \)
• \( C(M, s_1) = \neg a \land b \land EX(a \land \neg b) \land AX(a \land \neg b) \)

We can now state the formula that characterizes this structure:

\[
P(M, s_0) = C(M, s_0) \land \\
AG(C(M, s_0) \Rightarrow EXC(M, s_0) \land EXC(M, s_0) \land AX(C(M, s_0) \lor C(M, s_0))) \land \\
AG(C(M, s_0) \Rightarrow EXC(M, s_0) \land AXC(M, s_0)) \land \\
AG(C(M, s_0) \Rightarrow EXC(M, s_0) \land AXC(M, s_0))
\]

4. Equivalence With Respect To Stuttering

We first define what it means for two Kripke structures to be equivalent with respect to stuttering. Given two structures \( M \) and \( M' \) with the same set of atomic propositions, we define a sequence of equivalence relations \( E_0, E_1, \ldots \) on \( S \times S' \) as follows:

• \( s E_0 s' \) if and only if \( \mathcal{L}(s) = \mathcal{L}(s') \).

• \( s E_{n+1} s' \) if and only if

1. for every path \( \pi \) in \( M \) that starts in \( s \) there is a path \( \pi' \) in \( M' \) that starts in \( s' \), a partition \( B_1, B_2, \ldots \) of \( \pi \), and a partition \( B'_1, B'_2, \ldots \) of \( \pi' \) such that for all \( j \in \mathbb{N} \), \( B_j \) and \( B'_j \) are both non-empty and finite, and every state in \( B_j \) is \( E_n \)-related to every state in \( B'_j \), and

2. for every path \( \pi' \) in \( M' \) starting in \( s' \) there is a path \( \pi \) in \( M \) starting in \( s \) that satisfies the same condition as in 1.

Our notion of equivalent with respect to stuttering is defined as follows: \( s E s' \) if and only if \( s E_i s' \) for all \( i \geq 0 \). Furthermore, we say that \( M \) with initial state \( s_0 \) is equivalent to \( M' \) with initial state \( s'_0 \) if \( s_0 E s'_0 \).

**Lemma 12:** Given two Kripke structures \( M \) and \( M' \), there exists an \( i \) such that \( \forall s \forall s' \ [s E_i s' \iff s E s'] \).

**Proof:** By the definition of \( E_{i+1} \), \( s E_{i+1} s' \Rightarrow s E_i s' \), so \( E_0 \supseteq E_1 \supseteq E_2 \ldots \). Since \( M \) and \( M' \) are both finite, \( E_0 \) must be finite as well, so only a finite number of these containments can be proper. Let \( E_i \) be the last relation that is properly included in \( E_{i-1} \). By the definition of proper containment, \( \forall m \geq l [E_i = E_m] \), so \( s E_i s' = s E_m s' \), for \( m \geq l \). Since \( s E_i s' \Rightarrow s E_{i-1} s' \Rightarrow s E_{i-2} s' \ldots \), we have \( s E_i s' = \forall m [s E_m s'] \), so \( s E_i s' = s E s' \). The other direction is trivial. \( \square \)

**Theorem 13:** If \( s E s' \), then for every CTL* formula \( f \) without the nexttime operator, \( s \models f \iff s' \models f \).

The proof is similar to that of theorem 2.

**Lemma 14:** Given a Kripke structure \( M \), for every state \( s \in M \), there is a CTL formula \( C(M, s) \) such that \( \forall t \in M \ [t \models C(M, s) \iff s E t] \).
Proof: We will prove by induction on $l$.

- If $\neg(sE_l t)$, then there is a CTL formula $d_l(s,t)$ such that $\forall \nu \in M[sE_l \nu \Rightarrow \nu \models d_l(s,t)]$ and $t \not\models d_l(s,t)$.

- For every state $s \in M$, there is a CTL formula $C_l(M,s)$ such that for every $t \in M$, $t \models C_l(M,s)$ iff $sE_l t$.

$d_l(s,t)$ is a formula that distinguishes between $t$ and states equivalent to $s$ within the structure $M$, and $C_l(M,s)$ is a formula that characterizes $E_l$-equivalence to state $s$ within $M$.

If we let $C_l(M,s)$ be a conjunction of $C_{l-1}(M,s)$ and $d_l(s,t)$ for every $t$ that is not $E_l$-related to $s$, the second assertion follows easily. By lemma 12, this condition implies that the lemma is true. Now it is necessary to show how to construct $d_l(s,t)$ by induction on $l$.

**Basis ($l=0$):** Let $\{p_j\}$ be the set of atomic propositions in $L(s)$ and $\{q_j\}$ be the set of atomic propositions in $AP - L(s)$. Now, let $C_0(M,s) = d_0(s,t) = \bigwedge_i p_i \land \bigwedge_j \neg q_j$. It is clear that this formula is only true in states with the same labelling of atomic propositions as $s$. Therefore, the base case is established.

**Induction:** Assume that the result is true for $l$. We will show it for $l+1$.

Since $\neg(sE_{l+1} t)$, either there is a path from $s$ without a corresponding path from $t$, or vice versa. In the latter case, we will use the argument below to find a $d_{l+1}(t,s)$ such that $t \models d_{l+1}(t,s)$ and $s \not\models d_{l+1}(t,s)$. We can negate this formula to get the desired $d_{l+1}(s,t)$.

If there is a path from $s$ without a corresponding path from $t$, we can divide this path into blocks $(B_1, B_2, \ldots)$ such that:

$$\forall i [x \in B_i \Rightarrow x \models C_l(M, \text{first}(B_i)) \land \text{first}(B_{i+1}) \models C_l(M, \text{first}(B_i))].$$

Now, there are two cases: either there is a finite path from one state without a corresponding path from the other, or there is an infinite path without a corresponding path, but every finite prefix of this path has a corresponding path.

In the first case, the path from $s$ is finite, so the blocks are finite and there are only a finite number of them (say $n$). Consider the CTL formula:

$$d_{l+1}(s,t) = C_l(M, \text{first}(B_1)) \land E[C_l(M, \text{first}(B_2)) \lor C_l(M, \text{first}(B_3)) \land E[\ldots \lor C_l(M, \text{first}(B_n))] \ldots].$$

It is clear that $s \models d_{l+1}(s,t)$ along the path $B_1, B_2, \ldots, B_n$. However, if $t \models d_{l+1}(s,t)$ then there is a path that can be partitioned into blocks $B_1', B_2', \ldots, B_n'$ such that $\forall i [x \in B_i' \Rightarrow x \models C_l(M, \text{first}(B_i))].$ Since every state in $B_1'$
satisfies $C_i(M.\text{first}(B_i))$, the inductive hypothesis and the definition of $E_i$ gives $B_iE_iB_i'$. Therefore, this path from $i$ corresponds to the path from $s$, a contradiction. We conclude that $t \not\models d_{i+1}(s,t)$.

In the second case, we start by showing that the path from $s$ has only a finite number of blocks by using an argument based on König's lemma. We can construct a tree rooted at $i$ such that $t_1 \ldots t_n$ is a path through the tree if and only if there is a path in the Kripke structure $u_1 \ldots u_p \eta_1 \ldots \eta_q \ldots t_n$ that corresponds to a prefix of the path from $s$ with $B_i' = \langle u_1 \ldots u_p \rangle$, $B_i'' = \langle \eta_1 \ldots \eta_q \rangle$, and so on. Now, if the path from $s$ has an infinite number of blocks, this tree must have an infinite number of nodes. Otherwise, if the tree had $n$ nodes, there could be no path of length $n+1$, so the first $n+1$ blocks of the path from $s$ would have no corresponding path from $i$. Since the Kripke structure is finite, we also know that this tree must be finitely branching. Therefore, by König's lemma, there must be an infinite path through the tree. But this implies that there is an infinite path from $i$ that can be divided into an infinite number of blocks that correspond to the blocks of the path from $s$, so there is a path from $i$ corresponding to the path from $s$, violating our assumption. Therefore, the path from $s$ has only a finite number of blocks.

So, suppose that there are $n$ blocks, all of which are finite except the last. Consider the CTL formula:

$$d_{i+1}(s,t) = C_i(M.\text{first}(B_i)) \land E[C_i(M.\text{first}(B_i)) \cup C_i(M.\text{first}(B_i)) \land E[\ldots \cup \cup EG C_i(M.\text{first}(B_n))] \ldots]$$

It is clear that $s \models d_{i+1}(s,t)$ along the path $B_iB_2 \ldots B_n$. However, if $t \models d_{i+1}(s,t)$ then there is a path that can be partitioned into blocks $B_i' B_2' \ldots B_n'$ such that all of the blocks are finite except $B_n'$ and $\forall \nu \in B_i' \nu \models C_i(M.\text{first}(B_i))$. Since every state in $B_i$ satisfies $C_i(M.\text{first}(B_i))$, the inductive hypothesis and the definition of $E_i$ gives $B_iE_iB_i'$. We can also divide the infinite blocks $B_n$ and $B_n'$ into an infinite set of blocks containing one state each. Therefore, this path from $i$ corresponds to the path from $s$, so we have a contradiction. We conclude that $t \not\models d_{i+1}(s,t)$.

Now, these $d_{i+1}(s,t)$ describe the existence or nonexistence of a single path along which some $C_i$ formulas hold. By the definition of $s E_{i+1} \nu$, every path from $s$ has a corresponding path from $\nu$ along which the same $C_i$ formulas hold and vice versa. Therefore, $s E_{i+1} \nu \iff \nu \models d_{i+1}(s,t)$.

Therefore, the lemma is true. □

**Theorem 15:** Given a Kripke structure $M$ with initial state $s_0$, there is a CTL formula $F(M,s_0)$ that characterizes that structure up to $E$-equivalence with respect to stuttering, i.e. $M'.s'_n \models F(M,s_0) \iff s E s'_n$.

**Proof:** For any state $s$ in $M$, let $s_1, \ldots s_p$ be the extended successors of $s$, where an extended successor is a state that is not $E$-related to $s$ and is reachable from $s$ along a path consisting entirely of states that are $E$-equivalent to $s$. Next, we construct $G(M,s)$, which describes all of the transitions from $s$ in $M$. In this
construction, it is convenient to use the weak until operator, $\Lambda[\neg g \wedge \neg g]$, which differs from the ordinary until in that it permits an infinite path along which every state satisfies the first argument. So now:

$$G(M,s) = \begin{cases} 
\bigwedge \mathcal{E}[\mathcal{C}(M.s) \cup \mathcal{C}(M.s_i)] \wedge \Lambda[\mathcal{C}(M.s) \bigcup \bigvee \mathcal{C}(M.s_i)] \wedge \mathcal{E} \mathcal{C}(M.s) & \text{if } s \models \mathcal{E} \mathcal{G} \mathcal{C}(M.s) \\
\bigwedge \mathcal{E}[\mathcal{C}(M.s) \cup \mathcal{C}(M.s_i)] \wedge \Lambda[\mathcal{C}(M.s) \bigcup \bigvee \mathcal{C}(M.s_i)] \wedge \neg \mathcal{E} \mathcal{G} \mathcal{C}(M.s) & \text{otherwise}
\end{cases}$$

Let $F(M,s_0)$ be the formula $\mathcal{C}(M,s_0) \wedge \bigwedge \mathcal{A} \mathcal{G}(\mathcal{C}(M.s) \Rightarrow G(M,s))$.

The correctness of $F(M,s_0)$ is an easy consequence of the next two lemmas and theorem 13. □

Lemma 16: $s \models F(M.s)$.

Lemma 17: If $s \models F(M.t)$ and $s' \models F(M.t)$, then $s \mathcal{E} s'$.

Proof of Lemma 16: Since every state is trivially equivalent to itself, $s \models \mathcal{C}(M,s)$ is true by lemma 14. Therefore, if $s \models F(M.s)$ then there is a $t \in M$ such that $s \models \mathcal{E}(\mathcal{C}(M.t) \wedge \neg G(M.t))$. Let $\nu$ be the state reachable from $s$ that satisfies $\mathcal{C}(M.t) \wedge \neg G(M.t)$. By lemma 14, this condition implies $t \mathcal{E} \nu$, so $t$ and $\nu$ must satisfy the same CTL formulas (theorem 13). We will show that $t \models \neg G(M.t)$, giving a contradiction. There are four cases.

1. $t \models \mathcal{E}[\mathcal{C}(M.t) \cup \mathcal{C}(M.w)]$, for some extended successor of $t$, $w$. By the definition of extended successor, there is a path from $t$ to $w$ and the states on this path are $\mathcal{E}$-related to $t$. By lemma 14, these states must satisfy $\mathcal{C}(M.t)$. Since $w \models \mathcal{C}(M.w)$ is trivial, this path satisfies $\mathcal{C}(M.t) \cup \mathcal{C}(M.w)$, which is a contradiction.

2. $t \models \mathcal{E} \mathcal{C}(M.t)$. Since $\mathcal{E} \mathcal{C}(M.t)$ is a conjunct of $G(M.t)$ if and only if $t \models \mathcal{E} \mathcal{C}(M.t)$, we have an immediate contradiction.

3. $t \models \neg \mathcal{E} \mathcal{C}(M.t)$. Since $\mathcal{E} \neg \mathcal{C}(M.t)$ is a conjunct of $G(M.t)$ if and only if $t \models \mathcal{E} \mathcal{C}(M.t)$, we have an immediate contradiction.

4. $t \models \Lambda[\mathcal{C}(M.t) \bigcup \bigvee \mathcal{C}(M.w_i)]$. In this case, $t \models \mathcal{E}[\mathcal{C}(M.t) \cup (\neg \mathcal{C}(M.t) \wedge \bigwedge \mathcal{C}(M.w_i))]$. Let $t_1, \ldots, t_n$ be this path, where $t_n \models \neg \mathcal{C}(M.t) \wedge \bigwedge \mathcal{C}(M.w_i)$ and $\forall i < n [t_i \models \mathcal{C}(M.t)]$. By lemma 14, $\neg (t_n \mathcal{E} t)$ and $\forall i < n [t_i \mathcal{E} t]$. Therefore, $t_n$ is an extended successor of $t$. But since $t_n \models \mathcal{C}(M.t_n)$ is trivially true, $t_n \models \bigwedge \mathcal{C}(M.w_i)$ cannot be true, so we have a contradiction.

Therefore, the lemma is true. □
Proof of Lemma 17: Since \( s \models s' \) if and only if \( s \models E_is' \) for all \( i \geq 0 \), we will prove \( s \models F(M,t) \) and \( s' \models F(M,t) \) implies \( s \models E_is' \) by induction on \( i \).

**Basis** (\( i = 0 \)): Since \( s \models F(M,t) \), \( s \models C(M,t) \) and therefore \( s \models C_0(M,t) \). Similarly, \( s' \models C_0(M,t) \), so \( L(s) = L(t) = L(s') \). Therefore, \( s \models E_0s' \).

**Induction:** Assume that the result is true for \( i \). We will now show it for \( i + 1 \).

We want to show that every path, \( \pi \), from \( s \) has a corresponding path, \( \pi' \) from \( s' \). (The proof of the dual is identical.) We will use induction on the length of \( \pi \) to prove the slightly stronger result:

If \( |\pi| \leq n \), then there is a corresponding path \( \pi' \) such that for some \( v \in M \),

\[
\text{last}(\pi) \models F(M,v) \text{ and } \text{last}(\pi') \models F(M,v).
\]

**Basis** (\( |\pi| = 1 \)): In this case, \( \pi = \langle s \rangle \). Let \( B_1 = \langle s \rangle \) and \( \pi' = B'_1 = \langle s' \rangle \). By the outer inductive hypothesis, \( s \models F(M,t) \) and \( s' \models F(M,t) \) imply \( s \models E_is' \), so \( B_1 E_i B'_1 \). Therefore, the paths correspond. Since the last states of each path satisfy \( F(M,t) \), the base case is true.

**Induction:** Assume the result for \( |\pi| \leq n \). Suppose that \( \pi = s_1 s_2 \ldots s_m \) a path of length \( n + 1 \). Now, \( s_1 s_2 \ldots s_{n-1} \) is a path of length \( n \), so by the inner inductive hypothesis, there is a corresponding path \( \pi' \) such that \( \text{last}(\pi') \models F(M,v) \) and \( s_{n-1} \models F(M,v) \) for some \( v \in M \). Let \( B_1 B_2 \ldots B_m \) and \( B'_1 B'_2 \ldots B'_m \) be the partitions that show that these paths correspond. There are three cases.

1. \( s_n \models C(M,v) \). Since \( s_{n-1} \models F(M,v) \), we can infer that \( s_{n-1} \models A[C(M,v) \lor \bigvee_i C(M,w_i)] \), where \( w_i \) are the extended successors of \( v \). Since \( s_{n-1} \) is a path and \( s_n \) that doesn't satisfy \( C(M,v) \), we conclude that there must be an extended successor of \( v, x \), such that \( s_n \models C(M,x) \). Since \( s_n \) is a successor of \( s_{n-1} \), it must satisfy all of the AG formulas that \( s_{n-1} \) satisfies, so \( s_n \models F(M,x) \).

   From \( \text{last}(\pi') \models F(M,v) \) we can infer that \( \text{last}(\pi') \models C(M,v) \lor E[C(M,v) \lor C(M,x)] \). Therefore, there is a path \( s'_1 s'_2 \ldots s'_k \) where \( s'_1 = \text{last}(\pi') \), \( \forall i < k [s'_i \models C(M,v)] \), and \( s'_k \models C(M,x) \). Now let \( \pi = B_1 \ldots B_m \langle s_n \rangle \) and \( \pi' = B'_1 \ldots B'_{m-1} \langle B'_m, s'_2 \ldots s'_{k-1} \rangle \). Since \( s_n \) and \( s'_k \) both satisfy \( F(M,x) \), the outer induction hypothesis gives \( E_i E_j \langle s'_k \rangle \). Similarly, since the all the states in \( B_m B'_m \), and \( s'_2 \ldots s'_{k-1} \) satisfy \( F(M,v) \), they are all \( E_i \) related to each other. Therefore, \( \pi \) and \( \pi' \) correspond with \( \text{last}(\pi) \models F(M,x) \) and \( \text{last}(\pi') \models F(M,x) \).

2. \( s_n \models C(M,v) \) and \( v \models \text{EG } C(M,v) \). Since \( s_n \) must satisfy the same AG formulas as \( s_{n-1} \), \( s_n \models F(M,v) \). Now, \( \text{last}(\pi') \models F(M,v) \), so \( \text{last}(\pi') \models \text{EG } C(M,v) \). Therefore, \( \text{last}(\pi') \) must have a successor, \( s'_1 \), which also satisfies \( C(M,v) \). Since this state must also satisfy all of the AG formulas, \( s'_1 \models F(M,v) \). Therefore, by the outer induction hypothesis, \( s_n E_i s'_1 \). So if we let \( B_{m+1} = \langle s_n \rangle \) and \( B'_{m+1} = \langle s'_1 \rangle \), the paths correspond.
3. \( s_n \models C(M, v) \) and \( v \vdash EGC(M, v) \). By the reasoning above, \( s_n \models f(M, v) \), so \( s_n \models f_{last}(B'_n) \). Therefore, \( \pi \) corresponds to \( \pi' \) with the same partition except that \( s_n \) is added to \( B_m \).

We must also show that the blocks of the partitions are finite. The only problem is case 3, in which we might add an infinite number of states to a block of \( \pi \). In this case, each of the states added to \( B_m \) satisfy \( F(M, v) \), so if we add an infinite number of states to this block \( \text{first}(B_m) \models EGC(M, v) \) must be true. But since \( \text{first}(B_m) \models f(M, v) \), \( \text{first}(B_m) \models \neg EGC(M, v) \), so we have a contradiction. Therefore, all of the blocks of the partition must be finite.

Therefore, the lemma is true. \( \square \)

Corollary 18: Given two structures \( M \) and \( M' \) with initial states \( s_0 \) and \( s'_0 \) respectively, \( s_0 E s'_0 \) if and only if for all CTL $^*$ formulas \( f \) without the nexttime operator, \( M, s_0 \models f \iff M', s'_0 \models f \).

Corollary 19: Given two structures \( M \) and \( M' \) with initial states \( s_0 \) and \( s'_0 \) respectively, if there is a formula of CTL $^*$ without the nexttime operator that is true in one and false in the other, then there is also a formula of CTL without the nexttime operator that is true in the one and false in the other.

5. Algorithm For Stuttering Equivalence

In this Section we show how to compute the relation for equivalence with respect to stuttering for states within a single Kripke Structure \( M \). The method that we suggest is polynomial in the number of states of \( M \). To determine equivalence between states in two different Kripke structures \( M_1 \) and \( M_2 \), we form a Kripke structure \( M_{12} \) that is the disjoint union of these structures and check equivalence between the corresponding states in the combined structure.

We construct a relation \( C \) on \( S \times S \) that is identical to the relation \( E \) defined in Section 4. \( C = \bigcap_{\pi} C_{\pi} \) where \( C_{\pi} \) is defined as follows:

- \( C_0 = \{(s, s') \mid L(s) = L(s') \}\)

- In order to define \( C_{\pi+1} \) we must first define the set \( \text{NEXT}_{\pi+1}(s) \) of extended successors of \( s \). We define this set in terms of the set \( \text{ST}_{\pi+1}(s) \) of stuttering states of \( s \):

\[
\text{ST}_{\pi+1}^{k}(s) = \text{ST}_{\pi+1}^{k}(s) \cup \{s' \mid \exists s'' \in \text{ST}_{\pi+1}^{k}(s) \land s'' \rightarrow s' \land s' \in C_{\pi} \}
\]

\[
\text{NEXT}_{\pi+1}(s) = \{s' \mid s' \in \text{ST}_{\pi+1}(s) \land \exists s'' \in \text{ST}_{\pi+1}(s) [s'' \rightarrow s'] \}.
\]

We will also use a predicate \( \text{LOOP}_{\pi}(s) \) that is true iff there is a cycle containing only states in \( \text{ST}_{\pi}(s) \).
Now we can define $C_{n+1}$ as follows:

$$C_{n+1} = \{ (s,s') \mid \text{LOOP}_{n+1}(s) = \text{LOOP}_{n+1}(s') \land sC_{n}s' \land$$
$$\forall s_i \in \text{NEXT}_{n+1}(s) \exists s_i' \in \text{NEXT}_{n+1}(s') (s_i C_{n}s_i') \land$$
$$\forall s_i' \in \text{NEXT}_{n+1}(s') \exists s_i \in \text{NEXT}_{n+1}(s) (s_i C_{n}s_i')$$

Proof that the relation $C$ constructed above is actually equal to the relation $E$ defined in Section 4 will be given in the journal version of this paper. Since the inductive structures of the definitions of the two relations are different, it is necessary to split the proof into two parts: the first part shows that $E \subseteq C_i$ for every $i$; the second part shows that $C \subseteq E_i$ for every $i$.

Computing $\text{ST}_n$ requires time $O(|S|^3)$. Computing $C_{n+1}$ given $C_n$ requires time $O(|S|)$, since at most $|S|^2$ pairs of states must be checked and each pair requires $O(|S|^2)$ time to check. The algorithm terminates as soon as $C_n = C_{n+1}$. Since at any previous step $k$, $|C_{k+1}| < |C_k|$ and since $C_0$ has at most $|S|^2$ pairs of states, there are at most $|S|^3$ steps in the construction of $C$. It follows that the complexity of the entire algorithm is $O(|S|^6)$.

If we replace each equivalence class of $C$ by a single state, this algorithm can also be used to minimize the number of states in the structure.

6. Conclusion

The results of our paper have a number of surprising implications. For example, if a specification of a finite state concurrent program in $\text{CTL}^*$ is sufficiently detailed so that there is only one program (modulo one of our notions of equivalence) that meets the specification, then an equivalent specification could have been written in $\text{CTL}$ instead. Another surprising consequence is that if a $\text{CTL}^*$ formula is not equivalent to any $\text{CTL}$ formula, then it must have an infinite number of mutually inequivalent finite models. To see that this result is true, we first observe that since $\text{CTL}^*$ has the finite model property, it must be the case that if two $\text{CTL}^*$ formulas have the same finite models, they must have the same infinite models as well. Otherwise, if $f_i$ had an infinite model $M$ that was not a model of $f_j$, $f_i \land \neg f_j$ would have an infinite model, but no finite models, contradicting the finite model property of $\text{CTL}^*$ [5]. Therefore, we can characterize a $\text{CTL}^*$ formula by the set of finite models in which it is satisfied. If a $\text{CTL}^*$ formula is satisfied by only a finite number of equivalence classes of finite models, then the formula is equivalent to the disjunction of the $\text{CTL}$ formulas that characterize the individual equivalence classes.

There are a number of directions for further research. First, from our construction, it appears that the characteristic formula of a Kripke structure might be quite large. It would be nice to have a lower bound on the size of this formula in terms of the size of the Kripke structure. Also, we conjecture that the $O(|S|^6)$ algorithm in Section 5 can be improved significantly. Finally, it would be interesting to see which of our results carry over to Kripke structures with fairness constraints, i.e. Büchi automata.
