Program Invariants as Fixedpoints

E. M. Clarke, Durham, North Carolina

Received July 27, 1977; revised May 5, 1978

Abstract — Zusammenfassung

Program Invariants as Fixedpoints. We argue that soundness and relative completeness theorems for Floyd-Hoare Axiom Systems ([3], [5], [18]) are really fixedpoint theorems. We give a characterization of program invariants as fixedpoints of functionals which may be obtained in a natural manner from the text of a program. We show that within the framework of this fixedpoint theory, soundness and relative completeness results have a particularly simple interpretation. Completeness of a Floyd-Hoare Axiom System is equivalent to the existence of a fixedpoint for an appropriate functional, and soundness follows from the maximality of this fixedpoint. The functionals associated with regular procedure declarations are similar to the predicate transformers of Dijkstra; for non-regular recursions it is necessary to use a generalization of the predicate transformer concept which we call a relational transformer.

1.

1.1 Background

Proof systems for correctness of computer programs may be treated as formal logical systems. Of particular interest are deductive systems for partial correctness based on the use of invariant assertions. Examples of such systems are described by Floyd [10] and Hoare [14]. Formulas in Floyd-Hoare Axiom Systems are triples \( \{P\} A \{Q\} \) where \( A \) is a statement of the programming language and \( P \) and \( Q \) are predicates in the language of first order predicate calculus (the assertion language). A partial correctness formula \( \{P\} A \{Q\} \) is true iff whenever \( P \) is satisfied by the initial program state and \( A \) is executed, then either \( A \) will fail to terminate or \( Q \) will be satisfied by the final program state. An axiom or rule of inference is associated with each statement type in the programming language, e.g.
Proofs of correctness for programs are constructed by using the rules of inference for the individual statements together with a proof system for the assertion language.

Once a method of proof has been formalized, it becomes important to determine which steps in the proof process are most difficult. With Floyd-Hoare Axiom System experience shows that there are two main sources of difficulty: (1) choosing the correct program invariants (e.g. \( P \) in the WHILE axiom above) and (2) demonstrating the truth of formulas in the underlying assertion language. This observation is justified by the work of Cook [3] on relative completeness theorems for Floyd-Hoare Axiom Systems. Cook gives an axiom system for a subset of Algol including the WHILE statement and nonrecursive procedures. He proves that (a) if the assertion language satisfies a natural expressibility condition which guarantees the existence of program invariants, and (b) if there is a complete proof system for the assertion language (e.g. the set of true formulas of the assertion language), then a partial correctness formula is true iff it is provable. Extension of Cook’s work to other language features are discussed by Gorelick ([13], recursive procedures), Owicki ([21], concurrent processes), Clarke ([2], procedure parameters under various restrictions on scope of variables), and Cherniavsky ([1], loop languages). Incompleteness results for language features, such as call-by-name parameter passing, are given in Clarke [2] and in Lipton and Snyder [17].

1.2 New Results of this Paper

Completeness results appear to be an important tool in investigations of program correctness; however, many basic open questions remain about the derivation and interpretation of such results. Although proofs of soundness and completeness are often long and tedious, it seems that the underlying ideas are quite simple. Are there general theorems from which many different completeness results may be obtained as special cases? What is the relationship between Cook’s definition of completeness and the definition of completeness used in the earlier work of Martin [18] and de Bakker and Meertens [5]? Gorelick [13], for example, has shown that a set of three axioms gives completeness for a language with parameterless recursive procedures. De Bakker and Meertens [5], on the other hand, prove that an infinite pattern of inductive assertions is necessary to obtain completeness for the same class of programming languages. Is there a way of reconciling these apparently contradictory results?

In this paper we argue that the soundness and relative completeness theorems of Cook et al. are really fixedpoint theorems. We give a characterization of program invariants as maximal fixedpoints of functionals which may be obtained in a natural manner from the program text. We further show that within the framework of this fixedpoint theory soundness and relative completeness theorems have a very simple interpretation. Completeness of a Floyd-Hoare Axiom System is equivalent to the existence of a fixedpoint for an appropriate functional, and sound-
ness follows from the maximality of this fixedpoint. Although fixedpoint techniques were used in the study of program invariants as early as 1970 by Park [20], we believe that this is the first discussion of the extremely close relationship that exists between such fixedpoint results and the soundness and relative completeness theorems of Cook and others.

The functionals associated with regular recursive procedures (i.e. flowchartable recursions) are similar to the predicate transformers of Dijkstra ([8], [6], [12]). In order to treat non-regular recursions we must generalize the notion of a program invariant from a single predicate to a binary relation on predicates which is preserved by procedure calls. The appropriate functional in this case is a generalization of the predicate transformer concept which we call a relational transformer. The relational transformer maps a programming language statement into the partial correctness relation determined by that statement. Since this mapping is continuous, a fixedpoint theorem characterizing the partial correctness relations of recursive procedures may be obtained.

1.3 Outline of Paper

Section 2 describes a simple recursive programming language. Sections 3 and 4 contain the regular fixedpoint theorem and some of its applications. A general fixedpoint theorem for program invariants applying to nonregular recursions as well as regular recursions is given in Section 5. Applications of the general fixedpoint theorem, including a discussion of the relationship between the completeness results of de Bakker [5] and Gorelick [13], are given in Section 6. The paper concludes with a discussion of the results and some remaining open problems.

2. A Simple Recursive Programming Language (RPL)

Any formal treatment of program correctness must include a discussion of the underlying logical system in which the predicates describing a program's behavior are expressed. In this paper the underlying assertion language is a first order language with equality which we denote by AL. An interpretation I for AL consists of a set D (the domain of the interpretation), an assignment of functions on D to the function symbols of AL, and an assignment of predicates on D to the predicate symbols of AL. Once an interpretation I has been specified, meanings may be assigned to the variable-free terms and closed formulas of AL.

Let ID be the set of identifiers (i.e. variables) of AL, and let I be an interpretation for AL with domain D. A program state is a mapping from ID to D giving the "value" associated with each identifier. We denote the set of all program states by S. If t is a term of AL with variables x₁, x₂, ..., xₙ and s is a program state, then we use the notation t(s) to mean

\[
\begin{array}{c}
S(x₁, \ldots, xₙ) \\
x₁, \ldots, xₙ
\end{array}
\]

i.e. the term obtained from t by simultaneously substituting s(x₁) for x₁, ..., s(xₙ) for xₙ. Likewise we may define P(s) where P is a formula of AL.
Frequently it will be convenient to identify a predicate \( P \) with the set \( \{ s \mid I[P(s)] = \text{true} \} \) of program states which make \( P \) true. If this identification is made, then the power set \( 2^S \) will be the set of all possible predicates, \( \text{false} \) will correspond to the empty state set, and \( \text{true} \) will correspond to the set \( S \) of all program states. Also logical operations on predicates can be interpreted as set theoretic operations on subsets of \( S \), i.e. “or” becomes “union”, “and” becomes “intersection”, “not” becomes “complement”, and “implies” becomes “is a subset of”. In general there will be many sets of states which are not expressible by formulas of the assertion language \( AL \).

An \( RPL \) program is a pair \( \langle E, A \rangle \) where \( E \) is a list of \textit{procedure declarations} and \( A \) is a \textit{statement}. Procedure declarations have the form: “\( \text{PROC } X = \tau \)” where \( X \) is the \textit{procedure name} and \( \tau \) is the \textit{body of the procedure} (also a statement). A statement is either a \textit{compound statement} “\( \langle A_1; A_2 \rangle \)”, a \textit{conditional statement} “\( (b \rightarrow A_1, A_2) \)”, an \textit{assignment statement} “\( x := e \)”, a \textit{procedure call} “\( X \)” where \( X \) is a procedure name, or a \textit{null statement} “\( \text{NULL} \)”. To simplify the treatment of recursion we also allow the undefined statement “\( \text{\Omega} \)”. We will require that the boolean expressions of \( RPL \) conditionals be \textit{quantifier-free} formulas of \( AL \), and that the right-hand sides of \( RPL \) assignment statements be \textit{terms} in \( AL \). Thus, \textit{side-effects} are not permitted as a consequence of arithmetic or boolean expression evaluation.

The meaning of an \( RPL \) statement \( A \) can only be described once an interpretation \( I \) has been specified. Since the statement \( A \) may contain procedure calls, the meaning of \( A \) also depends on the set \( E \) of procedure declarations in the program in which \( A \) occurs. Relative to a particular interpretation \( I \) and set of procedure declarations \( E \), the meaning of \( A \) is a function \( M_{I,E} [A] : S' \rightarrow S' \) (\( S' = S \cup \{ \bot \} \) where \( \bot \) represents undefined) which gives the effect of the execution of \( A \) on the values of the identifiers occurring in \( A \). There are many ways that \( M = M_{I,E} \) can be defined — in terms of computation sequences as in [3] or as the least fixedpoint of a continuous functional as in [6]. We will simply list a number of the properties that \( M \) can be shown to satisfy regardless of the definition used.

2.1

**Proposition:**

(a) \( M [\Omega] (s) = \bot \)

(b) \( M [\text{NULL}] (s) = s \)

(c) \( M [x := e] (s) = s' \) where \( s' [e] = \begin{cases} s [v], x \neq v \\ I[e(s)] \text{ o.w.} \end{cases} \)

(d) \( M [(A_1; A_2)] (s) = M [A_2] (M [A_1] (s)) \)

(e) \( M [(b \rightarrow A_1, A_2)] (s) = \begin{cases} M [A_1] (s), s \in b \\ M [A_2] (s), \text{ o.w.} \end{cases} \)

(f) \( M [X] (s) = M [\tau] (s) \) where \( X \) is a procedure name and “\( \text{PROC } X = \tau \)” is a declaration in \( E \).

Let \( PF \) be the set of partial functions from \( S \) to \( S \), i.e. \( PF \) is the set of functions \( f : S' \rightarrow S' \) such that \( f (\bot) = \bot \). Let \( f_1, f_2 \in PF \); we write \( f_1 \sqsubseteq f_2 \) iff for all \( x \), \( f_1 (x) = \bot \) or \( f_1 (x) = f_2 (x) \). A sequence \( \{ f_i \}_{i \geq 0} \) of functions in \( PF \) is a \textit{chain} iff for
all \( i, f_i \subseteq f_{i+1} \). If \( \{ f_i \}_{i \geq 0} \) is a chain of partial functions, then \( \bigsqcup_{i \geq 0} f_i \) is the partial function defined by

\[
(\bigsqcup_{i \geq 0} f_i)(x) = \begin{cases} 
y & \text{if there exists a } j \geq 0 \text{ such that } f_i(x) = y \text{ for } i \geq j \\ \bot & \text{o.w.}
\end{cases}
\]

2.2

**Proposition:** Let \( X \) be a procedure name occurring in a program which contains the procedure declaration \("\text{PROC } X = \tau"\). Let the statement sequence \( \{ X^i \}_{i \geq 0} \) be defined inductively by \( X^0 = \Omega, X^{i+1} = \tau \xrightarrow{X} X^i \) then

(a) the sequence \( \{ M[X^i] \}_{i \geq 0} \) is a chain in \( \text{PF} \)
(b) \( M[X] = \bigsqcup_{i \geq 1} M[X^i] \).

Partial correctness formulas will have the form \( \langle P \rangle \ A \langle Q \rangle \) where \( A \) is a program statement and \( P \) and \( Q \) are formulas of the assertion language \( AL \).

2.3

**Definition:** \( \langle P \rangle \ A \langle Q \rangle \) is true with respect to \( I (\models_I \langle P \rangle \ A \langle Q \rangle) \) iff

\[ \forall s, s' \in S [s \in P \ A M[A](s) = s' \Rightarrow s' \in Q]. \]

If the interpretation \( I \) is clear from context we will simply write \( \models \langle P \rangle \ A \langle Q \rangle \). \( WP[A](Q) \) will denote the weakest precondition for partial correctness corresponding to the statement \( A \) and the post-condition \( Q \). \( WP[A](Q) \) is characterized by

(i) \( \models \langle WP[A](Q) \rangle \ A \langle Q \rangle \) and (ii) \( \models \langle P \rangle \ A \langle Q \rangle \Rightarrow \models P \Rightarrow WP[A](Q) \). In terms

(i) \( \models \langle WP[A](Q) \rangle \ A \langle Q \rangle \) and

(ii) \( \models \langle P \rangle \ A \langle Q \rangle \Rightarrow \models P \Rightarrow WP[A](Q) \).

In terms of the meaning function \( M, WP[A](Q) \) may be defined by \( WP[A](Q) = \{ s \in S | M[A](s) = \bot \) or \( M[A](s) \in Q \). The weakest precondition \( WP[A](Q) \) may not be expressible by a formula of the assertion language \( AL \). Cook [3] demonstrates this in the case in which the assertion language is Presburger arithmetic. Wand [25] gives another example of the same phenomenon.

2.4

**Definition:** The assertion language \( AL \) is expressive with respect to the interpretation \( I \) iff for all statements \( A \) and post-conditions \( Q \) in \( AL \), there is a formula of \( AL \) which expresses \( WP[A](Q) \).

Subsequently we will see that expressibility insures the existence of invariants for while loops and recursive procedures. Although some choices of \( AL \) and \( I \) do not give expressibility, many realistic choices do give expressibility; if \( AL \) is the full language of number theory and \( I \) is an interpretation in which the symbols of number theory receive their usual meanings, then \( AL \) will be expressive with respect to \( I \). Also if the domain of \( I \) is finite, expressibility is assured.
Likewise, $SP[A](P)$ will denote the strongest post-condition corresponding to statement $A$ and precondition $P$. $SP[A](P)$ is characterized by (i) \( \models_P \{P\} \succeq \{SP[A](P)\} \) and (ii) \( \models_P \{P\} \succeq \{Q\} \Rightarrow \models_P \{SP[A](P)\} \Rightarrow Q \). $SP[A](P)$ may also be defined in terms of the meaning function $M': SP[A](P) = \{M[A](s) \mid s \in P\}$. It is not difficult to show that weakest preconditions are expressible by formulas of $AL$ iff strongest post-conditions are also expressible. Thus an equivalent definition of “expressive” may be given in terms of $SP[A](P)$.

If $H$ is a Floyd-Hoare Axiom System and $T$ is a complete proof system for the language $AL$ with respect to $I$ (i.e. for the formulas of $AL$ which are true under interpretation $I$), then a proof in the system $(H, T)$ will consist of a sequence of partial correctness formulas $\{P\} \begin{array}{c} \models \{Q\} \end{array}$ and formulas of $AL$ each of which is either an axiom (of $H$ or $T$) or follows from previous formulas by a rule of inference (of $H$ or $T$). If $\{P\} \begin{array}{c} \models \{Q\} \end{array}$ occurs as a line in such a proof, then we write $\proves_{H,T} \{P\} \begin{array}{c} \models \{Q\} \end{array}$. In a similar manner, we may define $\pi_1 \proves_{H,T} \pi_2$ where $\pi_1$ and $\pi_2$ are sets of partial correctness assertions. If $H$ and $T$ are clear from context, we will write “$\proves$” instead of “$\proves_{H,T}$”.

2.5

**Definition (Cook):** A Floyd-Hoare Axiom System $H$ for a programming language $PL$ is sound and complete iff for all $AL$, $T$, and $I$ such that (a) $AL$ is expressive relative to $I$ and (b) $T$ is a complete proof system for $AL$ with respect to $I$, $\models_I \{P\} \begin{array}{c} \models \{Q\} \end{array}$.

3. The Regular Fixedpoint Theorem

This section contains the first of the two fixedpoint theorems which are the main technical results of the paper. These theorems characterize the invariants of a recursive procedure as (pre-) fixedpoints of a functional which may be obtained in a natural manner from the procedure’s declaration. Subsequently, we shall argue that these fixedpoint theorems are logically soundness and relative completeness theorems of Cook et al. The first fixedpoint theorem is for regular recursive procedures. In this case the associated functionals are similar to the predicate transformers of Dijkstra [8].

3.1

**Definition [5]:** Let $X$ be a procedure name, $\tau_1$ and $\tau_2$ statements. Then

(a) $X$ is regular in $X$.

(b) If $\tau_1$ does not contain $X$ and $\tau_2$ is regular in $X$, then $\tau_1; \tau_2$ is regular in $X$.

(c) If $\tau_1$ and $\tau_2$ are both regular in $X$, then $b \Rightarrow \tau_1; \tau_2$ is regular in $X$.

A procedure declaration “PROC $X = \tau$” is regular if $\tau$ is regular in $X$.

Thus, for example, PROC $X = (A_1; (b \Rightarrow (A_2 X), NULL))$ is regular in $X$, but PROC $X = (b \Rightarrow (A_1; X; A_2), A_3)$ is not.
Let "PROC X = τ" be a regular procedure declaration and let \( Q \subseteq S \) be a predicate. The partial correctness functional \( \Gamma : 2^S \rightarrow 2^S \) associated with \( X \) and \( Q \) is defined as follows: 
\[ \Gamma(U) = G(U, \tau, Q) \]
where
(A) \( G(U, A, R) = WP[A](R) \) if \( A \) does not contain any calls on procedure \( X \);
(B) \( G(U, (A_1; A_2), R) = G(U, A_1, G(U, A_2, R)) \);
(C) \( G(U, (b \rightarrow A_1, A_2), R) = (b \rightarrow G(U, A_1, R)) V \neg b \rightarrow G(U, A_2, R) \);
(D) \( G(U, X, R) = U \).

Note that \( G(U, \tau, Q) \) will be well-defined as long as \( \tau \) is regular in \( X \). Thus, for example, the partial correctness functional \( \Gamma \) associated with
\[ \text{PROC } X = (A_2; (b \rightarrow (A_2; X), NULL)) \]
and predicate \( Q \) is
\[ \Gamma(U) = WP[A_1](b \rightarrow WP[A_2](U)) V \neg b \rightarrow WP[NULL](Q). \]

3.2

Theorem (Regular Fixedpoint Theorem): Let "PROC X = τ" be a regular procedure declaration, \( Q \subseteq S \) be a predicate, and \( \Gamma \) be the partial correctness functional associated with \( X \) and \( Q \). Then \( WP[X](Q) \) is the unique maximal pre-fixedpoint of \( \Gamma \), i.e. the unique maximal solution of \( U \subseteq \Gamma(U) \).

Example: If \( \Gamma \) is the partial correctness functional associated with "PROC X = (A_2; (b \rightarrow (A_2; X), NULL))", then (i) \( WP[X](Q) \subseteq \Gamma(WP[X](Q)) \) and (ii) \( U \subseteq \Gamma(U) \) implies that \( U \subseteq WP[X](Q) \).

\( WP[X](Q) \) is also the unique maximal fixedpoint\(^1\) of \( \Gamma \). For our purposes, however, it will be easier to work with pre-fixedpoints rather than fixedpoints. Before giving the proof of Theorem 3.2, we must prove a number of lemmas which give key properties of weakest preconditions and the partial correctness functional \( \Gamma \).

3.5

Lemma: Let \( A \) be an RPL statement.

(A) (Monotonicity): If \( P \) and \( Q \) are predicates (subsets of \( S \)) and \( P \subseteq Q \), then \( WP[A](P) \subseteq WP[A](Q) \).

(B) (Additivity): If \( \{ P_i \}, i \geq 0 \) is a family of predicates, then
\[ WP[A](\bigcup_i P_i) = \bigcup_i WP[A](P_i), \quad WP[A](\bigcap_i P_i) = \bigcap_i WP[A](P_i). \]

Proof of (A): The proof is a direct application of the definition of \( WP[A](Q) \) in terms of the meaning function \( M \). Assume that \( P \subseteq Q \). If \( s \in WP[A](P) \), then either \( M[A](s) \) diverges or \( M[A](s) \in P \). Since \( P \subseteq Q \), it follows that either \( M[A](s) \) diverges or \( M[A](s) \in Q \). Thus \( s \in WP[A](Q) \). Proof of (B) is similar and will be left to the reader.

\(^1\) In fact, if the declaration of \( X \) does not contain calls on other procedures besides \( X \), we may prove that the fixedpoints of \( \Gamma \) form a complete lattice under the natural partial ordering on \( 2^S \). The top element of this lattice is the weakest precondition for partial correctness \( WP[X](Q) \) and the bottom element is the weakest precondition for total correctness \( WT[X](Q) \).
3.4

**Lemma:** Let \( X \) be a procedure name occurring in a program which contains the procedure declaration “PROC \( X = \tau \)”. \( Q \subseteq S \) be a predicate. Define the statement sequence \( \{ X^i \}_{i \geq 0} \) by induction \( X^0 = \Omega, X^{i+1} = \tau \frac{X^i}{X} \) then

(A) the sequence \( \{ WP[X](Q) \}_{i \geq 0} \) is a descending chain in \( 2^S \), i.e. for all \( i \geq 0 \)

\[
WP[X^{i+1}](Q) \subseteq WP[X^i](Q).
\]

(B) \( WP[X](Q) = \bigcap_{i \geq 0} WP[X^i](Q) \).

**Proof:** (Given in Appendix)

3.5

**Lemma:** Let \( \Gamma \) be the partial correctness functional corresponding to the regular procedure \( X \) and predicate \( Q \). Then

(A) If \( \{ V_i \}, i \geq 0 \) is a family of predicates in \( S \), then \( \Gamma \left( \bigcap_i V_i \right) = \bigcap_i \Gamma(V_i) \) and \( \Gamma \left( \bigcup_i V_i \right) = \bigcup_i \Gamma(V_i) \).

(B) \( U \subseteq V \) implies \( \Gamma(U) \subseteq \Gamma(V) \).

(C) Let the statement sequence \( X^i \) be defined as in Lemma 3.4. Then

\[
\Gamma(WP[X^i](Q)) = WP[X^{i+1}](Q).
\]

**Proof:** (A) follows directly from 3.3 (B) follows immediately from Lemma 3.5 (A). Since \( U \cup (V - U) = V \), we get \( \Gamma(U) = \Gamma(U) \cup \Gamma(V - U) \). It follows that \( \Gamma(U) \subseteq \Gamma(V) \).

To prove (C) we suppose that \( X \) has declaration “PROC \( X = \tau \)” and that \( \tau \) is regular in \( X \). Since \( X^{i+1} = \tau \frac{X^i}{X} \), we see that \( G(WP[X^i](Q), \tau, Q) = WP[X^{i+1}](Q) \).

By definition of \( \Gamma \), we obtain \( \Gamma(WP[X^i](Q)) = WP[X^{i+1}](Q) \).

We are now ready to complete the proof of the regular fixedpoint theorem (Theorem 3.2).

(i) \( WP[X](Q) \) is a fixedpoint of \( \Gamma \).

\[
\Gamma(WP[X](Q)) = \Gamma(\bigcap_i WP[X^i](Q)) = \bigcap_i \Gamma(WP[X^i](Q)) = \bigcap_i WP[X^{i+1}](Q) = WP[X](Q)
\]

(ii) \( V \subseteq \Gamma(V) \) implies \( V \subseteq WP[X](Q) \). Suppose that \( V \subseteq \Gamma(V) \) then \( V \subseteq WP[X^0](Q) \), since \( WP[X^0](Q) \) is true. Assume that \( V \subseteq WP[X^i](Q) \) then by Lemma 3.5 \( \Gamma(V) \subseteq \Gamma(WP[X^i](Q)) \). Since \( V \subseteq \Gamma(V) \), we get \( V \subseteq WP[X^{i+1}](Q) \). It follows that \( V \subseteq WP[X^i](Q) \) for all \( i \geq 0 \). Thus \( V \subseteq \bigcap_i WP[X^i](Q) \) or \( V \subseteq WP[X](Q) \).
This completes the proof of the regular fixedpoint theorem. We end this section by stating some additional properties of weakest preconditions which we will need in later sections. Proofs of these properties may be found in [6] or [19].

3.6

Proposition:
(a) \( WP [x := e] (Q) = Q ^{x \leftarrow e} \)
(b) \( WP [\text{NULL}] (Q) = Q \)
(c) \( WP [\Omega] (Q) = \text{true} \)
(d) \( WP [(A_1; A_2)] (Q) = WP [A_1] (WP [A_2] (Q)) \)
(e) \( WP [(b \rightarrow A_1, A_2)] (Q) = \{b \land WP [A_1] (Q) \} \cup \{ \neg b \land WP [A_2] (Q) \} \)
(f) \( WP [X] (Q) = WP [\tau] (Q) \) provided \( X \) has declaration “PROC \( X = \tau \)”.

4. Applications of the Regular Fixedpoint Theorem

To demonstrate the power of the regular fixedpoint theorem, we prove the soundness and completeness of a Floyd-Hoare Axiom System \( H_0 \) of the subset \( RPL_0 \) of the programming language \( RPL \). A statement in the language \( RPL_0 \) will be either: (1) an assignment statement, “\( x := e \)” ; (2) a conditional statement, “\( (b \rightarrow A_1, A_2) \)” ; (3) an iteration statement, “\( \text{LOOP} A_1 \text{WHILE} b \text{ DO} A_2 \text{ REPEAT} \)” ; or (4) a composition statement, “\( A_1; A_2 \)”. The iteration statement will be represented within the language \( RPL \) by a call on the procedure \( \text{PROC} X = (A_1; (b \rightarrow (A_2; X)), \text{NULL}) \).

For each basic statement type in the language \( RPL_0 \) there is a corresponding axiom or rule of inference in the deduction system \( H_0 \). These axioms and rules of inference are listed below:

1. \( \{Q ^{x \leftarrow e}\} x := e \{Q\} \) (assignment)
2. \( \{P \land b\} A_1 \{Q\}, \{P \land \neg b\} A_2 \{Q\} \)
   \( \frac{}{\{P\} (b \rightarrow A_1, A_2) \{Q\}} \) (conditional)
3. \( \{P\} A_1 \{R\}, \{R \land b\} A_2 \{P\}, \{R \land \neg b\} Q \)
   \( \frac{}{\{P\} \text{LOOP} A_1 \text{WHILE} b \text{ DO} A_2 \text{ REPEAT} \{Q\}} \) (iteration)
4. \( \{P\} A_1 \{R\}, \{R\} A_2 \{Q\} \)
   \( \frac{}{\{P\} (A_1; A_2) \{Q\}} \) (composition)
5. \( P \rightarrow R_1, \{R_1\} A \{R_2\}, R_2 \rightarrow Q \)
   \( \frac{}{\{P\} A \{Q\}} \) (consequence)

We will show that soundness and completeness of the deduction system \( H_0 \) are direct corollaries of the regular fixedpoint theorem. The question of soundness will be considered first. Let \( T \) be a sound proof system for the true formulas of the assertion language. We will prove that \( \vdash \text{true} \{P\} A \{Q\} \Rightarrow \vdash \{P\} A \{Q\} \). Since \( T \) is sound, it is sufficient to prove that each instance of an axiom is true; and
that if all of the hypotheses of a rule of inference are true, then the conclusion will be true also. We will only consider the case of the iteration statement. We assume that \( \models P \rightarrow WP[A_1](R) \), \( \models R \land b \rightarrow WP[A_2](P) \), and \( \models R \land \sim b \rightarrow Q \) hold, and prove that \( \models P \rightarrow WP[X](Q) \) must hold also.

From the regular fixedpoint theorem, we know that \( WP[X](Q) \) is the unique maximal pre-fixedpoint of \( \Gamma \) with respect to \( \sim Q \). From \( \models R \land b \rightarrow WP[A_2](P) \) and \( \models R \land \sim b \rightarrow Q \), we derive \( \models R \rightarrow \{ b \land WP[A_2](P) \} \sim b \land Q \). Since \( \models P \rightarrow WP[A_1](R) \) holds, we conclude that \( P \rightarrow WP[A_1](\{ b \land WP[A_2](P) \} \sim b \land Q) \) and consequently \( P \rightarrow WP[X](Q) \) are both true. Making use of the correspondence between \( \equiv \) and \( \rightarrow \) and the maximality of \( WP[X](Q) \), we see that \( P \subseteq WP[X](Q) \). Since \( P \subseteq WP[X](Q) \) is equivalent to \( \{ P \} \ X \{ Q \} \), the proof of soundness for the iteration statement is completed. We see that the soundness of the axiom for the iteration construct follows immediately from the characterization of the weakest precondition as a maximal fixedpoint.

We next show that the proof system \( H_0 \) is complete. Let \( T \) be a complete proof system for the true formulas of the assertion language. Assume also that the assertion language \( AL \) is expressive with respect to the interpretation \( I \). We prove that \( \models \{ P \} \ A \{ Q \} \Leftrightarrow \models_{H_0,T} \{ P \} \ A \{ Q \} \). The proof uses induction on the structure of the statement \( A \). We only consider the case of the iteration statement. Assume that \( \models \{ P \} \ X \{ Q \} \), where \( X \) has declaration \( PROC X = (A_1; (b \rightarrow (A_2; X), NULL)) \).

By the regular fixedpoint theorem,

\[
WP[X](Q) = WP[A_1](\{ b \land WP[A_2](WP[X](Q)) \} \sim b \land Q).
\]

Let \( R = \{ b \land WP[A_2](WP[X](Q)) \} \sim b \land Q \). \( R \) and \( WP[X](Q) \) are representable by formulas of \( AL \) because of the expressibility condition. Thus each of the following three formulas is true:

(a) \( \models WP[X](Q) = WP[A_1](R) \); (b) \( \models R \land b \rightarrow WP[A_2](WP[X](Q)) \); (c) \( \models R \land \sim b \rightarrow Q \).

Converting to precondition-postcondition notation and using the inductive hypothesis we obtain:

(a) \( \models WP[X](Q) \mid A_1 \{ R \} \); (b) \( \models R \land b \rightarrow WP[A_2](WP[X](Q)) \); (c) \( \models R \land \sim b \rightarrow Q \).

By the rule of inference for the iteration statement, it follows that \( \{ WP[X](Q) \mid LOOP A_1 WHILE b DO A_2 \ REPEAT \{ Q \} \) is provable. Since \( P \rightarrow WP[X](Q) \) is true and \( T \) is a complete proof system for the assertion language, \( P \rightarrow WP[X](Q) \) must be provable. By the rule of consequence it follows that \( \{ P \} \ LOOP A_1 WHILE b DO A_2 \ REPEAT \{ Q \} \) is provable also. Note that key to the completeness argument is the fact that \( WP[X](Q) \) is a fixedpoint of the partial correctness functional associated with the recursive procedure \( PROC X = (A_1; (b \rightarrow (A_2; X), NULL)). \)

Conversely, it is possible to prove that the soundness and completeness of the axiom system \( H_0 \) imply that \( WP[X](Q) \) is the unique maximal pre-fixedpoint of the partial correctness functional \( \Gamma \) associated with procedure \( X \) and postcondition \( Q \). Let \( H_0, T, \) and \( I \) be as previously described. Assume that for all statements \( A \) and predicates \( P, Q \) in \( AL, \models_{H_0,T} \{ P \} \ A \{ Q \} \iff \models_I \{ P \} \ A \{ Q \}. \)
(i): $WP [X] (Q)$ is a pre-fixedpoint of the partial correctness functional $\Gamma$. Since $\models WP [X] (Q) \wedge X \models Q$, we may use completeness to deduce the existence of predicates $U_1, R_1$, and $V_1$ in $AL$ with the properties:

(a) $\models WP [X] (Q) \rightarrow U_1$;  
(b) $\models U_1 \wedge X \models V_1$;  
(c) $\models U_1 \models A_1 \models R_1$;  
(d) $\models R_1 \models A \models b \rightarrow A \models U_1$;  
(e) $\models R_1 \models A \models b \rightarrow V_1$;  
(f) $\models V_1 \models Q$.

By soundness and (f) we obtain:

(a') $\models WP [X] (Q) \rightarrow U_1$;  
(b') $\models U_1 \wedge X \models Q$;  
(c') $\models U_1 \models A_1 \models R_1$;  
(d') $\models R_1 \models A \models b \rightarrow A \models U_1$;  
(e') $\models R_1 \models A \models b \rightarrow Q$.

Using the characterization of weakest preconditions in Section 2, we may rewrite (b')--(e') as follows:

(b'') $\models U_1 \models WP [X] (Q)$;  
(c'') $\models U_1 \models WP [A_1] (R_1)$;  
(d'') $\models R_1 \models A \models b \rightarrow WP [A_2] (U_1)$;  
(e'') $\models R_1 \models A \models b \rightarrow Q$.

From (d'') and (e'') we get: $\models R_1 \models (b \models A \models WP [A_2] (U_1)) \models V \models (b \models A \models Q)$.

From (c'') and monotonicity, $\models U_1 \models WP [A_1] (b \models A \models WP [A_2] (U_1)) \models V \models (b \models A \models Q)$ or $\models U_1 \models \Gamma (U_1)$.

From (a') and (b'') we see that $U_1$ and $WP [X] (Q)$ correspond to the same set of program states. Thus $WP [X] (Q) \models \Gamma (WP [X] (Q))$ and $WP [X] (Q)$ is a pre-fixedpoint of $\Gamma$.

(ii): If $U$ is a pre-fixedpoint of $\Gamma$, then $U \models WP [X] (Q)$. Suppose that $U$ is a pre-fixedpoint of $\Gamma$, then $\models U \models WP [A_1] (b \models A \models WP [A_2] (U)) \models V \models (b \models A \models Q)$.

If we choose $R = (b \models A \models WP [A_2] (U)) \models V \models (b \models A \models Q)$, then we may show:

(a) $\models U_1 \models A_1 \models R$;  
(b) $\models R \models A \models b \models A \models U_1$;  
(c) $\models R \models A \models b \rightarrow Q$.

By soundness of the axiom for the iteration statement, we get $\models U \models X \models Q$.

Using the characterization of weakest preconditions, $\models U \models WP [X] (Q)$ which is equivalent to $U \models WP [X] (Q)$.

5. The General Fixedpoint Theorem

The argument used to establish the regular fixedpoint theorem does not generalize to arbitrary recursive procedures. In fact, the partial correctness functional $\Gamma$ will not in general be defined for nonregular recursive procedures. In Section 6 we shall see that the additional complexity of nonregular recursions is also reflected in the proof rules for recursive procedures; it is impossible to adequately specify the meaning of a recursive procedure by means of a single predicate which is left invariant by the execution of a procedure call. In order to treat nonregular recursions we must generalize the notion of a program invariant from a single predicate to a binary relation on predicates which expresses the input-output behavior of the recursive procedure.
To express the invariants of arbitrary recursive procedures we introduce a generalization of the weakest precondition concept which we call the general correctness relation. The general correctness relation $GR$ maps a programming language statement into the partial correctness relation determined by that statement.

5.1

**Definition:** Let $REL$ be the universal relation on $2^S$, i.e. $REL = 2^S \times 2^S$. The general correctness relation $GR : ST \rightarrow 2^{REL}$ may be defined by

$$GR[A] = \{(P, Q) | P, Q \text{ are expressible in } AL \text{ and } P \subseteq WP[A] (Q)\}.$$ 

Since $(P, Q) \in GR[A]$ iff $\models \{P\} A \{Q\}$, the general correctness relation may be regarded as a notational device for emphasizing the functional relationship between a programming language statement and the partial correctness relation determined by the statement.

To obtain the general correctness relation for a composite program from the general correctness relations of its component parts we will need two operations on binary relations in addition to the standard set theoretic operations (union, intersection, etc.). The first operation is the standard composition operation for relations:

$$R_1 \circ R_2 = \{(U, W) | \exists V \in R_1 A (V, W) \in R_2\}.$$ 

The second operation is the "scalar multiplication" of a relation by a predicate:

$$b \ast R = \{(P, Q) | (P, Q) \in R\}.$$ 

Each of the properties of weakest preconditions listed in Propositions 3.4 and 3.5 of Section 3 has an exact analogue for the general correctness relation $GR$.

5.2

**Proposition:**

(a) $GR[\text{NULL}] = \{(P, Q) | P, Q \text{ are expressible in } AL \text{ and } \models P \rightarrow Q\}$

(b) $GR[x := e] = \{(P, P, P) | P \text{ is expressible in } AL\}$

(c) $GR[\tau] = REL$

(d) $GR[(A_1; A_2)] = GR[A_1] \circ GR[A_2]$

(e) $GR[(b \rightarrow A_1, A_2)] = (b \ast GR[A_1]) \cap (\sim b \ast GR[A_2])$

(f) $GR[X] = GR[\tau]$ where $X$ is a procedure with declaration "PROC $X = \tau$".

**Proof of (e):** $(P, Q) \in GR[(b \rightarrow A_1, A_2)]$ implies that $P \subseteq WP [[b \rightarrow A_1, A_2]] (Q)$. By Proposition 3.6 $P \subseteq WP [b \rightarrow A_1] (Q)$ and $P \cup WP [A_1] (Q)$ and $P \cup WP [A_1] (Q)$. Thus, $P \subseteq WP [A_1] (Q)$ and $P \subseteq WP [A_1] (Q)$. It follows that

$$(P, Q) \in (b \ast GR[A_1]) \cap (\sim b \ast GR[A_2]).$$

Since each of the above steps is reversible, we conclude that

$$GR[(b \rightarrow A_1, A_2)] = (b \ast GR[A_1]) \cap (\sim b \ast GR[A_2]).$$
5.3

**Proposition:** Let $X$ be a procedure name in a program which contains the procedure declaration "PROC $X = \tau". Define the statement sequence $\{X^i\}$, $i \geq 0$ by induction $X^0 = \Omega$, $X^{i+1} = \tau \frac{X^i}{X}$, then

(A) the sequence $\{GR[X^i]\}$, $i \geq 0$ is a descending chain in $2^{\text{REL}}$; i.e. for all $i \geq 0$

$$GR[X^{i+1}] \subseteq GR[X^i]$$

(B) $GR[X] = \bigcap \{GR[X^i]\}$

**Proof of (A):** Let $(P, Q) \in GR[X^{i+1}]$, then $P \subseteq WP[X^{i+1}](Q)$. But

$$WP[X^{i+1}](Q) \subseteq WP[X^i](Q).$$

Thus $P \subseteq WP[X^i](Q)$ and $(P, Q) \in GR[X^i]$. The proof of (B) is also simple and will be left to the reader.

To state the general fixedpoint theorem we will need an analogue of the partial correctness functional $I'$ defined in Section 3. Let "PROC $X = \tau" be an arbitrary RPL procedure declaration. Since we are now dealing with binary relations on predicates, the appropriate partial correctness functional $\Delta$ is a mapping from $2^{\text{REL}}$ to $2^{\text{REL}}$ which may be defined as follows: $\Delta(R) = H(R, \tau)$ where

(A) $H(R, A) = GR[A]$ if the statement $A$ does not contain any calls on procedure $X$;

(B) $H(R, (A_1; A_2)) = H(R, A_1) \cdot H(R, A_2)$;

(C) $H(R, (b \rightarrow A_1, A_2)) = (b \cdot H(R, A_1)) \cap (\sim b \cdot H(R, A_2))$;

(D) $H(R, X) = R$.

Note that $H(R, A)$ will be defined for both regular and nonregular statements $A$. For example, if $X$ has the nonregular declaration "PROC $X = (b \rightarrow (A_1; X; A_2, NULL)" then the associated partial correctness function is

$$\Delta(R) = (b \cdot GR[A_1] \circ R \cdot GR[A_2]) \cap (\sim b \cdot GR[NULL]).$$

5.4

**Theorem (General Fixedpoint Theorem):** Let "PROC $X = \tau" be an arbitrary RPL procedure declaration, and let $\Delta$ be the associated partial correctness functional. Then $GR[X]$ is the unique maximal pre-fixedpoint of $\Delta$, i.e. the unique maximal solution to $R \sqsubseteq \Delta(R)$.

The proof of the general fixedpoint theorem uses essentially the same idea as the proof of the regular fixedpoint theorem and will not be given in full here. To illustrate how the proof works we consider the special case in which the procedure $X$ has declaration "PROC $X = (b \rightarrow (A_1; X; A_2, NULL)". We prove that $GR[X]$ is the unique maximal pre-fixedpoint of

$$\Delta(R) = (b \cdot GR[A_1] \circ R \cdot GR[A_2]) \cap (\sim b \cdot GR[NULL]).$$
To see that \( GR [ X] \) is a fixedpoint of \( A \) note that:
\[
A ( GR [ X]) \equiv \left( b \ast GR [ A_1] \ast GR [ X] \ast GR [ A_2] \ast ( \sim b \ast GR [ NULL]) \right) \cap ( \sim b \ast GR [ NULL]) = GR [ X].
\]
To see that \( GR [ X] \) is maximal, assume that \( R \subseteq A ( R) \). Then
(1) \( R \subseteq REL \equiv GR [ X^0] \).
(2) if \( R \subseteq GR [ X'] \) then \( R \subseteq A ( R) \subseteq A ( GR [ X']) = GR [ X^{i+1}] \).

Thus, by induction \( R \subseteq GR [ X^i] \) for \( i \geq 0 \). It follows that \( R \subseteq \bigcap_i GR [ X^i] \) or \( R \subseteq GR [ X] \).

6. Applications of the General Fixedpoint Theorem

6.1 Nonregular Recursions and the Completeness Theorem of deBakker and Meertens

Suppose that we interpret the \( RPL_0 \) iteration statement of Section 4 as a call on the nonregular procedure \( \text{PROC } X = (b \rightarrow (A_1; X; A_2), \text{NULL}) \) instead of the regular procedure \( \text{PROC } X = (A_1; (b \rightarrow (A_2; X), \text{NULL}) \). What would be an appropriate rule of inference for this modified version of the iteration statement? A first choice might be
\[
\begin{align*}
\frac{\{ P A b \}, A_1; \{ P \}, P A \sim b \rightarrow Q, \{ Q \}, A_2; \{ Q \}}{\{ P \}, X; \{ Q \}}. 
\end{align*}
\]
(1)

It is not difficult to show that (1) is sound; an argument similar to the one in Section 4 may be used. Unfortunately, neither (1) nor any similar rule of inference gives completeness when used in conjunction with the other rules of inference of \( H_0 \). To see that (1) does not give completeness, consider the procedure declaration \( \text{PROC } Y = (b \rightarrow (A_1; Y, A_2)) \). A good rule of inference for \( Y \) is
\[
\begin{align*}
\frac{\{ P A b \}, A_1; \{ P \}, \{ P A \sim b \}, \{ A_2 \}, \{ Q \}}{\{ P \}, Y; \{ Q \}}. 
\end{align*}
\]
(2)

Since \( Y \) is regular, the reader may use the techniques of Section 4 to show that (2) gives both soundness and completeness. Next, let \( P_0, Q_0, \) and \( I \) be such that \( \{ P_0 \}, X; \{ Q_0 \} \) is true with respect to \( I \) but \( \{ P_0 \}, Y; \{ Q_0 \} \) is false. For example, choose
\[
\begin{align*}
b & \equiv n > 0 \quad P_0 \equiv n = n_0 \\
A_1 & \equiv n = n - 1 \quad Q_0 \equiv n = n_0 \\
A_2 & \equiv n = n + 1 \quad \end{align*}
\]

If (1) gave completeness, there would be formulas \( U_0 \) and \( V_0 \) expressible in the assertion language \( AL \) such that:
\[
\begin{align*}
a) & \quad \vdash \; P_0 \rightarrow U_0, \quad (b) & \quad \vdash \{ U_0 \}, \; b \rightarrow A_1; \{ U_0 \}; \\
b) & \quad \vdash \; U_0; \; i \rightarrow b \rightarrow V_0; \quad (c) & \quad \vdash \; U_0; \; i \sim b \rightarrow V_0; \\
c) & \quad \vdash \; V_0; \; i \rightarrow V_0; \quad (d) & \quad \vdash \; V_0; \; i \rightarrow V_0; \\
n) & \quad \vdash \; V_0; \; i \rightarrow V_0, \quad (e) & \quad \vdash \; V_0; \; i \rightarrow V_0.
\end{align*}
\]
Combining (c) and (d), we get $\vdash \{U_0 \cdot i \cdot b\} A_1 \{U_0\} \vdash \{U_0 \cdot i \sim b\} A_2 \{V_0\}$.
By axiom (2) it follows that $\vdash \{U_0\} Y \{V_0\}$. From the rule of consequence, $\vdash \{P_0\} Y \{Q_0\}$ which is a contradiction.

A general version of the above argument is used by Fokkinga [11] to argue that an infinite pattern of assertions is necessary in order to obtain completeness for nonregular recursions. In [5], de Bakker and Meertens attach a pair of assertions to each node in the infinite tree obtained by unwinding the recursive declaration (“the tree of incarnations”). In the case of the linear recursion

\[
\text{"PROC } X = (b \rightarrow A_1; \ A_2; \ NULL"},
\]

they obtain proof scheme:

\[
\begin{align*}
P & \rightarrow P_0 \\
\{P, A \ b\} A_1 \{P_{i+1}\} & \\
P_i \ A \sim b \rightarrow Q_i & \\
\{Q_{i+1}\} A_2 \{Q_i\} & \\
Q_0 & \rightarrow Q \\
P & \rightarrow P \{Q\}
\end{align*}
\]

(3)

Similar proof schemes may be obtained for other nonregular recursions; however, for many of these recursions, it is necessary to index the predicates by strings in $(0 + 1)^n$ rather than integers.

The general fixedpoint theorem may be used to prove the soundness and completeness of this extended version of the inductive assertion method. To illustrate how such a proof may be constructed we prove the soundness and completeness of (3) above.

To prove soundness we assume that $\{P, A \ b\} A_1 \{P_{i+1}\}$, $P_i \ A \sim b \rightarrow Q_i$, and $\{Q_{i+1}\} A_2 \{Q_i\}$ are true for all $i \geq 0$ and show that $\{P_0\} X \{Q_0\}$ must be true also. Let $K = \{(P_i, Q_i) | i \geq 0\}$ then $K \subseteq (b \ast GR \ [A_1] \ K \ast GR \ [A_2]) \cap (\sim b \ast GR \ [NULL])$. By the general fixedpoint theorem GR [X] is the unique maximal pre-fixedpoint of \(J(R) = (b \ast GR \ [A_1] \ R \ast GR \ [A_2]) \cap (\sim b \ast GR \ [NULL])\). Hence $K \subseteq GR \ [X]$ and consequently $\vdash \{P_0\} X \{Q_0\}$.

To prove completeness, we assume that $\models \{P_0\} X \{Q_0\}$, i.e. $(P_0, Q_0) \in GR \ [X]$. By the general fixedpoint theorem

\[
GR \ [X] = (b \ast GR \ [A_1] \ G R \ [X] \ast GR \ [A_2]) \cap (\sim b \ast GR \ [NULL]).
\]

By expressibility, there exists a pair of predicates $P_0, Q_0$ such that

\[
(Q_1, Q_0) \in GR \ [A_2] \quad (4)
\]

(1 $P_0, Q_0) \in GR \ [X] \quad (5)

(1 $P_0, A \ b, P_1) \in GR \ [A_1] \quad (6)

(1 $P_0, A \sim b, Q_0) \in GR \ [NULL] \quad (7)

In precondition-postcondition notation (4), (5), and (7) may be rewritten as

\[
\models \{P_0 \cdot b \ast A_1 \}; P_1.
\]

(4')
\[
\begin{align*}
\models & \{Q_1\} A_2 \{Q_0\} \quad (5') \\
\models & P_0 \ A \sim b \rightarrow Q_0 \quad (7')
\end{align*}
\]

This process may be continued to obtain \( P_2, Q_2, P_3, Q_3, \ldots \).

Note that the general fixedpoint theorem was used in exactly the same way that the
regular fixedpoint theorem was used in Section 4. Completeness of the rule scheme
for procedure \( X \) follows from the existence of a fixedpoint to the partial corre-
ctness functional \( A \) associated with \( X \). Soundness is obtained from the maximality
of the fixedpoint.

The argument used by deBakker and Meertens for the necessity of rules of inference involving
infinitively many hypothesis is based on a treatment of predicates as sets of program states. If predicates are
formulas in the first order predicate calculus, and assertions are allowed to contain variables which are not
changed by the program, then simpler rules of inference may be obtained. Such a proof system based on the
work of Cook and Gorelick is given in the next section. Alternatively the proof system of Cook and Gorelick may be viewed as a way of
organizing or indexing the predicates in the system of deBakker and Meertens.

6.2 The Completeness Theorem of Cook and Gorelick

The deduction system which we consider in this chapter is based on “induction
on depth of recursion” and is a modification of the deduction system described by
of this system, we must introduce some additional terminology.

6.2.1

**Definition:** Let \( A \) be a statement in a RPL program \( J \). A variable \( u \) is active in
\( A \) if and only if:

(i) \( A \) is an assignment statement and \( u \) occurs in the right or left side of \( A \).

(ii) \( A \) is a conditional statement “\( b \rightarrow A_1, A_2 \)” and \( u \) occurs in \( b \), \( u \) is active in \( A_1 \),
or \( u \) is active in \( A_2 \).

(iii) \( A \) is a composite statement “\( \langle A_1 ; A_2 \rangle \)” and \( u \) is active in \( A_1 \) or \( u \) is active in \( A_2 \).

(iv) \( A \) is a call on a procedure \( X \) with declaration “\( \text{PROC } X \equiv \tau \)” occurring in the
declaration part of \( J \) and \( u \) is active in \( \tau \).

If \( u \) is not active in \( A \), then \( u \) is said to be inactive.

Intuitively, a variable \( u \) is inactive in the statement \( A \) if \( u \) is not changed by
the execution of \( A \) and if the value of \( u \) does not influence the results of the
execution of \( A \). The definition of inactive may be extended to terms and to
substitutions of terms for variables.

6.2.2

**Definition:** A term \( t \) is inactive if the only variables occurring in \( t \) are inactive
variables. A substitution \( \sigma \) is an inactive substitution if \( \sigma \) is a substitution of
inactive terms for inactive variables.
The deduction system $CG$ for arbitrary recursive procedures consists of seven axioms. The first axioms are called the basic partial correctness axioms; they are the assignment axiom, the axiom for the null statement, the rule of composition, the rule of the conditional, and the rule of consequence. We refer the reader to Section 4 for statements of these axioms. The two remaining axioms are needed to handle recursive procedures. The first axiom is an induction axiom which allows proofs to be constructed by induction on depth of recursion.

$$CG1\quad \frac{\{P\} X \{Q\} \vdash \{P\} \tau \{Q\}}{\{P\} X \{Q\}} \quad \text{(recursion)}$$

where $X$ has declaration "PROC $X = \tau$".

The second axiom is used to adapt a general induction hypothesis about what a recursive procedure does to a specific call on the procedure.

$$CG2\quad \frac{\{P\} A \{Q\}}{\exists \bar{e} [P \sigma A T] A \{Q \sigma A T\}} \quad \text{(adaptation)}$$

provided that

(a) $T$ does not contain any free variables which are active in $A$.
(b) $\sigma$ is an inactive substitution.
(c) the variables $\bar{e}$ are inactive with respect to $A$.

We illustrate the use of these axioms by proving $\{n=n_0\} X \{n=[n_0/2]\}$ where $X$ is the procedure with declaration PROC $X=(n>0 \rightarrow (n:=n-2; X; n:=n+1))$ NULL. To simplify notation, let $P$ be the predicate $\{n=n_0\}$, $Q$ be the predicate $\{n=[n_0/2]\}$, and $T$ the predicate $\{n_1=n_0-2\}$. We begin by assuming that $\{P\} X \{Q\}$ is true.

If $\sigma$ is the inactive substitution $\sigma=\frac{n_1}{n_0}$, then

(a) $\{P A n>0\} n:=n-2 \exists n_1 [P \sigma A T]$ and  (b) $\exists n_1 [Q \sigma A T] n:=n+1 \{Q\}$

are both provable. By the inductive hypothesis and $CG2,

(c) $\exists n_1 [P \sigma A T] X \{Q \sigma A T\}$

is also provable. Using the rule of consequence to combine (a), (b), and (c), we obtain

$$\vdash \{P A n>0\} n:=n-2; X; n:=n+1 \{Q\}.$$  

Since $\{P A \sim b\}$ NULL $\{Q\}$ is also provable, the conditional rule may be used to show

$$\vdash \{P\} (n>0 \rightarrow (n:=n-2; X; n:=n+1)) \text{ NULL} \{Q\}.$$  

By the rule of recursion $CG1$, we obtain $\vdash \{P\} X \{Q\}$.

The deduction system $CG$ may be shown to be sound and complete for proving partial correctness of RPL programs provided that such programs do not involve recursive cycles of procedure calls [13], i.e. provided that procedures are always declared before they are used. The completeness proof may be extended to general RPL programs by using a more general version of the rule of recursion.
CG1. We will outline how soundness and completeness proofs for GR may be obtained as a by-product of the general fixedpoint theorem. To simplify the proof, we will only consider the case of a single recursive procedure X.

Recall that $SP[A](P)$ is the strongest postcondition associated with statement A and precondition P. Since the meaning of a procedure is usually given by an assertion about how the procedure transforms its input variables, it is convenient to use strongest postconditions rather than weakest preconditions in the proof of soundness and completeness for CG.

6.3

**Lemma:** Let $A$ be a statement in an RPL program J and let $P$ be a predicate in AL.

(a) If $Q$ is a formula of AL which does not contain any free variables which are active in $A$, then $SP[A](P \land Q) = SP[A](P) \land Q$.

(b) If the substitution $\sigma$ is inactive with respect to $A$, then $SP[A](P \sigma) = SP[A](P) \sigma$.

(c) If the variables $\bar{c}$ are inactive with respect to $A$, then $SP[A](\exists \bar{c}(P)) = \exists \bar{c}(SP[A](P))$.

Proofs of (a), (b), and (c) follow directly from the definition of $SP$ and will be left to the reader.

6.4

**Definition:** Let $P, Q$ be formulas of the assertion language AL and let $X$ be a procedure. The partial correctness relation determined by $P$ and $Q$ is the set $R[P, Q]$ of all ordered pairs of formulas $(U, V)$ such that for some choice of variable list $\bar{c}$, substitution $\alpha$, and $T$ the following three conditions are satisfied: (1) $\bar{c}$, $\alpha$, and $T$ are all inactive with respect to $X$; (2) $U \rightarrow \exists \bar{c}(P \alpha \land T)$; (3) $\exists \bar{c}(Q \alpha \land T) \rightarrow V$.

Intuitively, $R[P, Q]$ is the set of precondition/postcondition pairs which may be deduced from $\{P\} X \{Q\}$ by means of the rule of consequence and the rule of adaptation. By choosing $T$ to be the predicate true, $\alpha$ to be the identity substitution, and $\bar{c}$ to be a list of variables not appearing in $P$ or $Q$, we see that the pair $(P, Q)$ is itself an element of $R[P, Q]$.

6.5

**Lemma:** Let $P \equiv \exists \bar{w} = \bar{w}_0$ and $Q \equiv \{SP[A](\bar{w} = \bar{w}_0)\}$ where $\bar{w}$ is the list of variables which are active in $A$ and $\bar{w}_0$ is a list of new inactive variables having the same length as $\bar{w}$, then $GR[A] \subseteq R[P, Q]$.

**Proof:** Let $(P', Q') \in GR[A]$ then $\models SP[A](P') \rightarrow Q'$. Note that $P \equiv \exists \bar{w}_1 \left[ \bar{w} = \bar{w}_1 \land P' \frac{\bar{w}_1}{\bar{w}} \right] \equiv \exists \bar{w}_1 [P \alpha \land T]$ where $\bar{w}_1$ is a list of new variables which are inactive in $X$, $\alpha$ is the inactive substitution $\frac{\bar{w}_1}{\bar{w}_0}$, and $T$ is the inactive predicate $\frac{P' \bar{w}_1}{\bar{w}}$. Thus, $\models SP[A](\exists \bar{w}_1 [P \alpha \land T]) \rightarrow Q'$.

By Lemma 6.3 we see that $\models \exists \bar{w}_1 \left[ SP[A](P \alpha \land T) \rightarrow Q' \right]$. Since $SP[A](P) = Q$, it follows that $\models \exists \bar{w}_1 [Q \alpha \land T] \rightarrow Q'$. 

6.6

Lemma: Assume that AL is expressive with respect to I and that T is a complete proof system for the true formulas of AL. Let X be an RPL procedure declaration "PROC X = τ", and let Δ be the partial correctness functional associated with X. Then \{P\} X \{Q\} ⊨ \{P’\} τ \{Q’\} holds iff (P’, Q’) ∈ Δ (R [P, Q]).

Proof: Proof of Lemma 6.6 involves an induction on the structure of τ. A full proof of this lemma is given in the Appendix.

Soundness of the System CG: To prove the soundness of CG, we must show that each instance of an axiom is true and that if all of the hypothesis of a rule of inference are true, then the conclusion will be true also. The soundness of the five basic partial correctness axioms and the rule of adaptation CG2 may be proved in a straightforward manner, and will be left as exercises to the reader. To prove the soundness of the rule of recursion CG1 we assume that

\{P\} X \{Q\} ⊨ \{P\} τ \{Q\} \tag{1}

where X is a procedure with declaration "PROC X = τ". Let Δ be the partial correctness functional associated with X. By the general fixedpoint theorem, we know that GR [X] is the unique maximal pre-fixedpoint of Δ.

The partial correctness relation R [P, Q] is also a pre-fixedpoint of Δ; to see this, let (U, V) ∈ R [P, Q] with |= U → 3 c [P σ A T] and |= 3 c [Q σ A T] → V. From (1) and the rule of adaptation we see that \{P\} X \{Q\} ⊨ \{3 c [P σ A T]\} τ \{3 c [Q σ A T]\}. By the rule of consequence \{P\} X \{Q\} ⊨ \{U\} τ \{V\}. By Lemma 6.6 it follows that (U, V) ∈ Δ (R [P, Q]).

Since GR [X] is the unique maximal pre-fixedpoint of Δ, R [P, Q] ⊆ GR [X]. Since (P, Q) ∈ R [P, Q], we see that (P, Q) ∈ GR [X] or equivalently that |= \{P\} X \{Q\}.

Completeness of the System CG: To prove the completeness of CG, we must show that if AL is expressive with respect to I and T is a complete proof system for the true formulas of AL, then |= \{U\} A \{V\} implies |= CG, T \{U\} A \{V\}. The proof is by induction on the structure of A. We will only consider the case where A is a call on the procedure X; other cases are simpler and will be left to the reader. Let P = {\overrightarrow{w} = \overrightarrow{w}_0} and Q = SP [X] {\overrightarrow{w} = \overrightarrow{w}_0} where \overrightarrow{w} and \overrightarrow{w}_0 are defined in Lemma 6.5. By Lemma 6.5, GR [X] ⊆ R [P, Q]. Let Δ be the partial correctness functional associated with X. By the general fixedpoint theorem GR [X] is a pre-fixedpoint of Δ, i.e. GR [X] ⊆ Δ (GR [X]). Since Δ is monotonic, GR [X] ⊆ Δ (R [P, Q]). Since |= \{P\} X \{Q\}, (P, Q) ∈ GR [X] ⊆ Δ (R [P, Q]). Thus \{P\} X \{Q\} ⊨ \{P\} τ \{Q\} by Lemma 6.6. By the rule of recursion, we obtain \{U\} X \{V\}. If |= \{U\} X \{V\} then (U, V) ∈ GR [X] ⊆ R [P, Q]. By Lemma 6.6 it follows that \{P\} X \{Q\} ⊨ \{U\} X \{V\}. Since \{P\} X \{Q\}, we conclude that |= \{U\} X \{V\} as required.

7. Conclusion

In this paper we have demonstrated how soundness and relative completeness theorems may be viewed as fixedpoint theorems for functionals. We believe that this alternative point of view sheds light on the meaning of soundness and relative
completeness results and promises to simplify the derivation of such results. We are currently attempting to extend this fixedpoint theory to additional programming language features such as parallelism [21]. We believe that the approach outlined in this paper may also be helpful in understanding recent incompleteness theorems for Floyd-Hoare Axiom Systems ([2], [17]). These theorems use classical undecidability techniques to show that for certain programming language constructs it is impossible to obtain axiom systems which give soundness and relative completeness. We conjecture that for many programming language constructs it may be easier to prove the nonexistence of a fixedpoint than to prove an undecidability results. Finally, we are exploring the question of whether the explicit formulas for program invariants given in Section 3 may be used to automatically generate invariants of loops and recursive procedures. The work of Suzuki [24] and Cousot [4] suggests that invariants can indeed be generated in this manner.

Appendix

Proof of Lemma 3.4 (A): Let \( s \in WP[X^{i+1}](Q) \) then \( M[X^{i+1}](s) = \perp \) or there is an \( s' \) such that \( M[X^{i+1}](s) = s' \) and \( s' \in Q \). If \( M[X^{i+1}](s) = \perp \), then \( M[X^i](s) = \perp \) also. If \( M[X^{i+1}](s) = s' \) then either \( M[X^i](s) = \perp \) or \( M[X^i](s) = s' \) and \( s' \in Q \). Thus in either case \( s \in WP[X^i](Q) \).

Proof of Lemma 3.4 (B): Let \( s \in WP[X](Q) \) then either \( M[X](s) = \perp \) or there is an \( s' \) such that \( M[X](s) = s' \) and \( s' \in Q \). Thus either for all \( i \geq 0 \), \( M[X^i](s) = \perp \) or there is a \( j \) such that \( i \geq j \) implies \( M[X^j](s) = s' \). But this implies that for each \( i \) either \( M[X^j](s) = \perp \) or there is an \( s' \) such that \( M[X^j](s) = s' \) and \( s' \in Q \). It follows that \( s \in WP[X^i](Q) \) for all \( i \). Hence \( s \in \bigcap_{i \geq 0} WP[X^i](Q) \) and thus \( WP[X](Q) \subseteq \bigcap_{i \geq 0} WP[X^i](Q) \).

Conversely, let \( s \in \bigcap_{i \geq 0} WP[X^i](Q) \), then for all \( i \geq 0 \), \( s \in WP[X^i](Q) \). So for all \( i \geq 0 \), \( M[X^i](s) = \perp \) or there exists an \( s' \in S \) such that \( M[X^i](s) = s' \) and \( s' \in Q \). Since the sequence \( M[X^i](s) = \) is a chain, we get that either for all \( i \geq 0 \) \( M[X^i](s) = \perp \) or there exists \( s' \) and \( j \) such that \( i \geq j \) implies \( M[X^j](s) = s' \) and \( s' \in Q \). Hence \( M[X](s) = \perp \) or there is an \( s' \) such that \( M[X](s) = s' \) and \( s' \in Q \). This means that \( s \in WP[X](Q) \). We conclude that \( \bigcap_{i \geq 0} WP[X^i](Q) \subseteq WP[X](Q) \).

Proof of Lemma 6.6: Assume that \( AL \) is expressive with respect to \( I \) and that \( T \) is a complete proof system for the true formulas of \( AL \). We prove that for all statements \( A, \{P\} X \{Q\} \vdash \{P'\} A \{Q'\} \) iff \( (P', Q') \in H(R \{P, Q\}, A) \) where \( H \) is the auxiliary function used in the definition of \( A \). (\( \Leftarrow \)) Proof is by induction on the structure of \( A \). If \( A \) does not contain a call on procedure \( X \), then \( H(R \{P, Q\}, A) = GR[A] \). Since \( (P', Q') \in GR[A] \) implies that \( \vdash \{P'\} A \{Q'\} \) and since the basic partial correctness axioms are complete for RPL programs not involving recursion, we conclude \( \vdash \{P'\} A \{Q'\} \).

If \( A = (A_1; A_2) \) then \( H(R \{P, Q\}, A) = H(R \{P, Q\}, A_1) \circ H(R \{P, Q\}, A_2) \). If \( (P', Q') \in H(R \{P, Q\}, A) \) then by the expressibility condition there exists a formula
U of AL such that \((P^*, U) \in H(R[P, Q], A_1)\) and \((U, Q') \in H(R[P, Q], A_2)\). By the induction hypothesis, \(\{P\} X \{Q\} \vdash \{P\} A_1 \{U\}\) and \(\{P\} X \{Q\} \vdash \{U\} A_2 \{Q'\}\). By the rule of composition it follows that \(\{P\} X \{Q\} \vdash \{P\} (A_1; A_2) \{Q'\}\).

The case of the conditional statement i.e. \(A = \{b \to A_1, A_2\}\) is similar to the case of the composite statement and will be left to the reader. If \(A\) is a call on the procedure \(X\), then \(H(R[P, Q], A) = R[P, Q]\) and \((P', Q') \in [P, Q]\) implies that there exists \(\bar{c}, \bar{\sigma},\) and \(T\) as described in Definition 6.4 such that \(\vdash P' \exists \bar{c}[P \sigma A T]\) and \(\vdash \exists \bar{c}[Q \sigma A T] \to Q'\). By the rule of adaptation and the rule of consequence it follows that \(\{P\} X \{Q\} \vdash \{P\} A \{Q'\}\). \((\Rightarrow)\) Proof is by induction on the length of the proof of \(\{P\} A \{Q'\}\) from \(\{P\} X \{Q\}\). We will only consider the cases in which the last line of the proof was obtained by the use of the rule of composition or the rule of adaptation. If the last line was obtained by the rule of composition, then \(\{P\} X \{Q\} \vdash \{P\} A_1 \{U\}\) and \(\{P\} X \{Q\} \vdash \{U\} A_2 \{Q'\}\) where \(A = (A_1; A_2)\). By the inductive assumption \((P, U) \in H(R[P, Q], A_1)\) and \((U, Q') \in H(R[P, Q], A_2)\). Since \(H(R[P, Q], A) = H(R[P, Q], A_1) \circ H(R[P, Q], A_2)\), it follows that \((P', Q') \in H(R[P, Q], A)\). If the last line was obtained by the rule of adaptation, then \(A\) is simply a call on procedure \(X\). Furthermore there exist inactive \(\bar{c}, \bar{\sigma},\) and \(T\) such that \(\vdash P' \exists \bar{c}[P \sigma A T]\) and \(\vdash \exists \bar{c}[Q \sigma A T] \to Q'\). Since \(H(R[P, Q], A) = R[P, Q]\) in this case, it follows that \((P', Q') \in H(R[P, Q], A)\).
