15-780: Graduate Artificial Intelligence

Decision trees

Graphical models

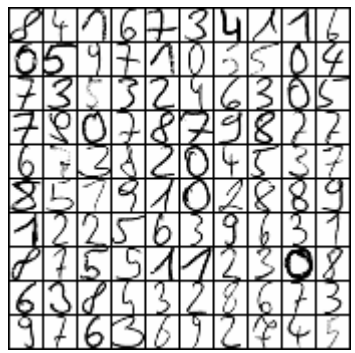
- So far we discussed models that capture joint probability distributions
- These have many uses, and can also be used to determine binary values for variables

  - For example, did a burglary occur?
- However, they also require us to make many assumptions and to fit many parameters:

  - model structure
  - probability model
  - model parameters

Classification

- In many cases we are only interested in one specific variable.
- Examples:
  - Does the robot have to turn? Slow down?
  - What digit is in each of the squares?
  - Does the patient have cancer?



Generative vs. discriminative models

- Graphical models can be used for classification

  - They represent a subset of classifiers known as ‘generative models’

- But we can also design classifiers that are more specific to a given task and do not require an estimation of joint probabilities

  - These are often referred to as discriminative models

- Examples:

  - Support vector machines (SVM)

  - Decision trees

Decision trees

- One of the most intuitive classifiers
- Easy to understand and construct
- Surprisingly, also works very (very) well*

Lets build a decision tree!

* More on this towards the end of this lecture

Structure of a decision tree

- Internal nodes correspond to attributes (features)
- Leafs correspond to classification outcome
- edges denote assignment

Netflix offers $1 million prize for better movie recommendations
By MICHAEL LIEDTKE, AP Business Writer
Sunday, October 1, 2006
(10-01) 21:05 PDT San Francisco (AP) --
Online DVD rental pioneer Netflix Inc. wants recommendations on how to improve its movie-recommendation system so badly that it's dangling a $1 million reward as an incentive.
The prize, offered in a contest scheduled to begin Monday, is part of Netflix's effort to sharpen its competitive edge as it continues a bitter duel with Blockbuster Inc. and prepares for an anticipated onslaught of services that make it easier to download movies on to computer hard drives.

Building a decision tree

```
Function BuildTree(n,A)    // n: samples (rows), A: attributes
  If empty(A) or all n(L) are the same
      status = leaf
      class = most common class in n(L)
  else
      status = internal
      a ⇐ bestAttribute(n,A)
      LeftNode = BuildTree(n(a=1), A \ {a})
      RightNode = BuildTree(n(a=0), A \ {a})
   end
end
```

Building a decision tree

```
Function BuildTree(n,A)    // n: samples (rows), A: attributes
   If empty(A) or all n(L) are the same
      status = leaf
      class = most common class in n(L)
   else
      status = internal
      a ⇐ bestAttribute(n,A)
      LeftNode = BuildTree(n(a=1), A \ {a})
      RightNode = BuildTree(n(a=0), A \ {a})
    end
end
```

n(L): Labels for samples in this set

We will discuss this function next

Recursive calls to create left and right subtrees, n(a=1) is the set of samples in n for which the attribute a is 1

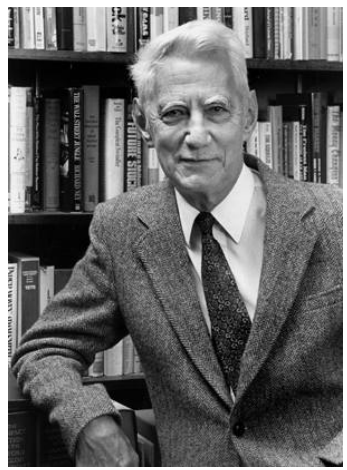
Identifying ‘bestAttribute’

- There are many possible ways to select the best attribute for a given set.
- We will discuss one possible way which is based on information theory and generalizes well to non binary variables

Entropy

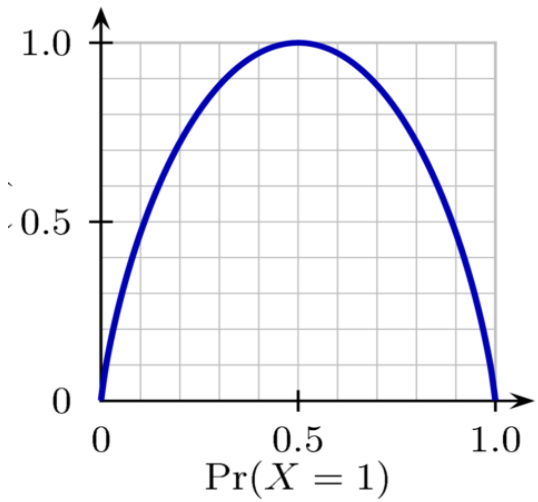
- Quantifies the amount of uncertainty associated with a specific probability distribution
- The higher the entropy, the less confident we are in the outcome
- Definition

$$H(X) = \sum_{c} - p(X = c) \log_2 p(X = c)$$



Claude Shannon (1916 – 2001), most of the work was done in Bell labs

Entropy



- Definition

$$H(X) = \sum_i -p(X = i)\log_2 p(X = i)$$

- So, if P(X=1) = 1 then

$$H(X) = -p(x = 1)\log_2 p(X = 1) - p(x = 0)\log_2 p(X = 0)$$
$$= -1\log 1 - 0\log 0 = 0$$

- If P(X=1) = .5 then

$$H(X) = -p(x = 1)\log_2 p(X = 1) - p(x = 0)\log_2 p(X = 0)$$
$$= -.5\log_2 .5 - .5\log_2 .5 = -\log_2 .5 = 1$$

Interpreting entropy

- Entropy can be interpreted from an information standpoint
- Assume both sender and receiver know the distribution. How many bits, on average, would it take to transmit one values?
- If P(X=1) = 1 then the answer is 0 (we don't need to transmit anything)
- If P(X=1) = .5 then the answer is 1 (either values is equally likely)
- If 0<P(X=1)<.5 or 0.5<P(X=1)<1 then the answer is between 0 and 1

  - Why?

Expected bits per symbol

- Assume P(X=1) = 0.8
- Then P(11) = 0.64, P(10)=P(01)=.16 and P(00)=.04
- Lets define the following code
  - For 11 we send 0
  - For 10 we send 01
  - For 01 we send 011
  - For 00 we send 0111

Expected bits per symbol

- Assume P(X=1) = 0.8
- Then P(11) = 0.64, P(10)=P(01)=.16 and P(00)=.04
- Lets define the following code
  - For 11 we send 0
  - For 10 we send 01
  - For 01 we send 011
  - For 00 we send 0111

so: 01001101111000110111101

can be broken to: 01 0 011 011 0 0 011 0111 01

which is: 10 11 01 11 11 01 00 01

- What is the expected bits / symbol?
  (.64*1+.16*2+.16*3+.04*4)/2 = 0.8
- Entropy (lower bound) H(X)=0.7219

Conditional entropy

Movie length	Liked?

Short	Yes
Long	Yes
Medium	Yes

- Entropy measures the uncertainty in a specific distribution
- What if both sender and receiver know something about the transmission?
- For example, say I want send the label (liked) when the length is known
- This becomes a conditional entropy problem: H(Li | Le=v)

Is the entropy of Liked among movies with length v

Conditional entropy: Examples for specific values

Movie length	Liked?
Short	Yes
Short	No
Medium	Yes
long	No
Long	No
Medium	Yes
Short	Yes
Long	Yes
Medium	Yes

Lets compute H(Li | Le=v)

1. H(Li | Le = S) = .92
2. H(Li | Le = M) = 0
3. H(Li | Le = L) = .92

Conditional entropy

Short	Yes
Long	Yes
Medium	Yes

- We can generalize the conditional entropy idea to determine H(Li | Le)
- That is, what is the expected number of bits we need to transmit if both sides know the value of Le for each of the records (samples)
- Definition: $H(X \mid Y) = \sum_i P(Y = i) H(X \mid Y = i)$

We explained how to compute this in the previous slides

Conditional entropy: Example

$$H(X \mid Y) = \sum_i P(Y = i) H(X \mid Y = i)$$

Movie length	Liked?
Short	Yes
Short	No
Medium	Yes
long	No
Long	No
Medium	Yes
Short	Yes
Long	Yes
Medium	Yes

- Lets compute H(Li | Le)

H(Li | Le) = H(Le = S) H(Li | Le=S)+

H(Le = M) H(Li | Le=M)+

H(Le = L) H(Li | Le=L) =

1/3*.92+1/3*0+1/3*.92 =

0.61

we already computed:

H(Li | Le = S) = .92

H(Li | Le = M) = 0

H(Li | Le = L) = .92

Information gain

- How much do we gain (in terms of reduction in entropy) from knowing one of the attributes
- In other words, what is the reduction in entropy from this knowledge
- Definition: $IG(X|Y)^* = H(X)-H(X|Y)$

*$IG(X|Y)$ is always ≥ 0

Proof: Jensen inequality

Where we are

- We were looking for a good criteria for selecting the best attribute for a node split
- We defined the entropy, conditional entropy and information gain
- We will now use information gain as our criteria for a good split
- That is, BestAttribute will return the attribute that maximizes the information gain at each node

Example: Root attribute

P(Li=yes) = 2/3

H(Li) = .91

H(Li | T) =

H(Li | Le) =

H(Li | D) =

H(Li | F) =

Additional points

- The algorithm we gave reaches homogonous nodes (or runs out of attributes)
- This is dangerous: For datasets with many (non relevant) attributes the algorithm will continue to split nodes
- This will lead to overfitting!

Avoiding overfitting: Tree pruning

- Split data into train and test set
- Build tree using training set

- For all internal nodes (starting at the root)
  - remove sub tree rooted at node
  - assign class to be the most common among training set
  - check test data error
    - if error is lower, keep change
    - otherwise restore subtree, repeat for all nodes in subtree

Continuous values

- Either use threshold to turn into binary or discretize
- Its possible to compute information gain for all possible tresholds (there are a finite number of training samples)
- Harder if we wish to assign more than two values (can be done recursively)

The ‘best’ classifier

- There has been a lot of interest lately in decision trees.
- They are quite robust, intuitive and, surprisingly, very accurate
