Program Optimization

15-213: Introduction to Computer Systems
10th Lecture, Oct. 1, 2015

Instructors:
Randal E. Bryant and David R. O’Hallaron
Today

■ Overview

■ Generally Useful Optimizations
  ▪ Code motion/precomputation
  ▪ Strength reduction
  ▪ Sharing of common subexpressions
  ▪ Removing unnecessary procedure calls

■ Optimization Blockers
  ▪ Procedure calls
  ▪ Memory aliasing

■ Exploiting Instruction-Level Parallelism

■ Dealing with Conditionals
Performance Realities

- **There’s more to performance than asymptotic complexity**

- **Constant factors matter too!**
  - Easily see 10:1 performance range depending on how code is written
  - Must optimize at multiple levels:
    - algorithm, data representations, procedures, and loops

- **Must understand system to optimize performance**
  - How programs are compiled and executed
  - How modern processors + memory systems operate
  - How to measure program performance and identify bottlenecks
  - How to improve performance without destroying code modularity and generality
Optimizing Compilers

- **Provide efficient mapping of program to machine**
  - register allocation
  - code selection and ordering (scheduling)
  - dead code elimination
  - eliminating minor inefficiencies

- **Don’t (usually) improve asymptotic efficiency**
  - up to programmer to select best overall algorithm
  - big-O savings are (often) more important than constant factors
    - but constant factors also matter

- **Have difficulty overcoming “optimization blockers”**
  - potential memory aliasing
  - potential procedure side-effects
Limitations of Optimizing Compilers

- **Operate under fundamental constraint**
  - Must not cause any change in program behavior
    - Except, possibly when program making use of nonstandard language features
    - Often prevents it from making optimizations that would only affect behavior under pathological conditions.

- **Behavior that may be obvious to the programmer can be obfuscated by languages and coding styles**
  - e.g., Data ranges may be more limited than variable types suggest

- **Most analysis is performed only within procedures**
  - Whole-program analysis is too expensive in most cases
  - Newer versions of GCC do interprocedural analysis within individual files
    - But, not between code in different files

- **Most analysis is based only on static information**
  - Compiler has difficulty anticipating run-time inputs

- **When in doubt, the compiler must be conservative**
Generally Useful Optimizations

- Optimizations that you or the compiler should do regardless of processor/compiler

- Code Motion
  - Reduce frequency with which computation performed
    - If it will always produce same result
    - Especially moving code out of loop

```c
void set_row(double *a, double *b, long i, long n)
{
    long j;
    for (j = 0; j < n; j++)
        a[n*i+j] = b[j];
}
```

```c
long j;
int ni = n*i;
for (j = 0; j < n; j++)
    a[ni+j] = b[j];
```
Compiler-Generated Code Motion (-O1)

```c
void set_row(double *a, double *b, long i, long n)
{
    long j;
    for (j = 0; j < n; j++)
        a[n*i+j] = b[j];
}
```

```assembly
set_row:
    testq  %rcx, %rcx          # Test n
    jle .L1                      # If 0, goto done
    imulq %rcx, %rdx            # ni = n*i
    leaq (%rdi,%rdx,8), %rdx    # rowp = A + ni*8
    movl $0, %eax               # j = 0
    .L3:
        movsd (%rsi,%rax,8), %xmm0 # t = b[j]
        movsd %xmm0, (%rdx,%rax,8) # M[A+ni*8 + j*8] = t
        addq $1, %rax             # j++
        cmpq %rcx, %rax           # j:n
        jne .L3                   # if !=, goto loop
    .L1:
        rep ; ret               # done:
```
Reduction in Strength

- Replace costly operation with simpler one
- Shift, add instead of multiply or divide
  \[ 16 \times x \rightarrow x \ll 4 \]
  - Utility machine dependent
  - Depends on cost of multiply or divide instruction
    - On Intel Nehalem, integer multiply requires 3 CPU cycles
- Recognize sequence of products

```c
for (i = 0; i < n; i++) {
    int ni = n*i;
    for (j = 0; j < n; j++)
        a[ni + j] = b[j];
}
```

```c
int ni = 0;
for (i = 0; i < n; i++) {
    for (j = 0; j < n; j++)
        a[ni + j] = b[j];
    ni += n;
}
```
Share Common Subexpressions

- Reuse portions of expressions
- GCC will do this with –O1

```c
/* Sum neighbors of i,j */
up = val[(i-1)*n + j ];
down = val[(i+1)*n + j ];
left = val[i*n + j-1];
right = val[i*n + j+1];
sum = up + down + left + right;
```

3 multiplications: i*n, (i-1)*n, (i+1)*n

```asm
leaq 1(%rsi), %rax  # i+1
leaq -1(%rsi), %r8  # i-1
imulq %rcx, %rsi  # i*n
imulq %rcx, %r8  # (i+1)*n
imulq %rcx, %r8  # (i-1)*n
addq %rdx, %rsi  # i*n+j
addq %rdx, %r8  # (i+1)*n+j
addq %rdx, %r8  # (i-1)*n+j
```

1 multiplication: i*n

```asm
long inj = i*n + j;
up = val[inj - n];
down = val[inj + n];
left = val[inj - 1];
right = val[inj + 1];
sum = up + down + left + right;
```

```asm
imulq %rcx, %rsi  # i*n
addq %rdx, %rsi  # i*n+j
movq %rsi, %rax  # i*n+j
subq %rcx, %rax  # i*n+j-n
leaq (%rsi,%rcx), %rcx  # i*n+j+n
```
Optimization Blocker #1: Procedure Calls

- Procedure to Convert String to Lower Case

```c
void lower(char *s)
{
    size_t i;
    for (i = 0; i < strlen(s); i++)
        if (s[i] >= 'A' && s[i] <= 'Z')
            s[i] -= ('A' - 'a');
}
```

- Extracted from 213 lab submissions, Fall, 1998
Lower Case Conversion Performance

- Time quadruples when double string length
- Quadratic performance
Convert Loop To Goto Form

```c
void lower(char *s)
{
    size_t i = 0;
    if (i >= strlen(s))
        goto done;
    loop:
        if (s[i] >= 'A' && s[i] <= 'Z')
            s[i] -= ('A' - 'a');
        i++;
        if (i < strlen(s))
            goto loop;
    done:
}
```

- `strlen` executed every iteration
Calling_strlen

/** My version of strlen */
size_t strlen(const char *s)
{
    size_t length = 0;
    while (*s != '\0') {
        s++;
        length++;
    }
    return length;
}

- **strlen performance**
  - Only way to determine length of string is to scan its entire length, looking for null character.

- **Overall performance, string of length N**
  - N calls to strlen
  - Require times N, N-1, N-2, ..., 1
  - Overall O(N^2) performance
Movin g Performance

void lower(char *s)
{
    size_t i;
    size_t len = strlen(s);
    for (i = 0; i < len; i++)
        if (s[i] >= 'A' && s[i] <= 'Z')
            s[i] -= ('A' - 'a');
}

- Move call to strlen outside of loop
- Since result does not change from one iteration to another
- Form of code motion
Lower Case Conversion Performance

- Time doubles when double string length
- Linear performance of lower2
Optimization Blocker: Procedure Calls

Why couldn’t compiler move strlen out of inner loop?

- Procedure may have side effects
  - Alters global state each time called
- Function may not return same value for given arguments
  - Depends on other parts of global state
  - Procedure lower could interact with strlen

Warning:

- Compiler treats procedure call as a black box
- Weak optimizations near them

Remedies:

- Use of inline functions
  - GCC does this with –O1
    - Within single file
- Do your own code motion

```c
size_t lencnt = 0;
size_t strlen(const char *s) {
    size_t length = 0;
    while (*s != '\0') {
        s++; length++;
    }
    lencnt += length;
    return length;
}
```
Memory Matters

/* Sum rows is of n X n matrix a and store in vector b */
void sum_rows1(double *a, double *b, long n) {
    long i, j;
    for (i = 0; i < n; i++) {
        b[i] = 0;
        for (j = 0; j < n; j++)
            b[i] += a[i*n + j];
    }
}

# sum_rows1 inner loop
.L4:
    movsd (%rsi,%rax,8), %xmm0    # FP load
    addsd (%rdi), %xmm0           # FP add
    movsd %xmm0, (%rsi,%rax,8)    # FP store
    addq  $8, %rdi
    cmpq  %rcx, %rdi
    jne   .L4

- Code updates $b[i]$ on every iteration
- Why couldn’t compiler optimize this away?
Memory Aliasing

/* Sum rows is of n X n matrix a
   and store in vector b */
void sum_rows1(double *a, double *b, long n) {
    long i, j;
    for (i = 0; i < n; i++) {
        b[i] = 0;
        for (j = 0; j < n; j++)
            b[i] += a[i*n + j];
    }
}

double A[9] = 
{ 0,  1,  2,  
  4,  8,  16},
  32,  64, 128};

sum_rows1(A, B, 3);

- Code updates \( b[i] \) on every iteration
- Must consider possibility that these updates will affect program behavior

Value of B:

<table>
<thead>
<tr>
<th>i</th>
<th>Value of B</th>
</tr>
</thead>
<tbody>
<tr>
<td>init</td>
<td>[4, 8, 16]</td>
</tr>
<tr>
<td>i = 0</td>
<td>[3, 8, 16]</td>
</tr>
<tr>
<td>i = 1</td>
<td>[3, 22, 16]</td>
</tr>
<tr>
<td>i = 2</td>
<td>[3, 22, 224]</td>
</tr>
</tbody>
</table>
Removing Aliasing

/* Sum rows is of n X n matrix a 
   and store in vector b */
void sum_rows2(double *a, double *b, long n) {
    long i, j;
    for (i = 0; i < n; i++) {
        double val = 0;
        for (j = 0; j < n; j++)
            val += a[i*n + j];
        b[i] = val;
    }
}

# sum_rows2 inner loop
.L10:
    addsd (%rdi), %xmm0  # FP load + add
    addq $8, %rdi
    cmpq %rax, %rdi
    jne .L10

- No need to store intermediate results
Optimization Blocker: Memory Aliasing

- **Aliasing**
  - Two different memory references specify single location
  - Easy to have happen in C
    - Since allowed to do address arithmetic
    - Direct access to storage structures
  - Get in habit of introducing local variables
    - Accumulating within loops
    - Your way of telling compiler not to check for aliasing
Exploiting Instruction-Level Parallelism

- Need general understanding of modern processor design
  - Hardware can execute multiple instructions in parallel
- Performance limited by data dependencies
- Simple transformations can yield dramatic performance improvement
  - Compilers often cannot make these transformations
  - Lack of associativity and distributivity in floating-point arithmetic
Benchmark Example: Data Type for Vectors

/* data structure for vectors */
typedef struct{
    size_t len;
    data_t *data;
} vec;

/* retrieve vector element and store at val */
int get_vec_element(*vec v, size_t idx, data_t *val)
{
    if (idx >= v->len)
        return 0;
    *val = v->data[idx];
    return 1;
}

Data Types

- Use different declarations for data_t
- int
- long
- float
- double
Benchmark Computation

```c
void combine1(vec_ptr v, data_t *dest) {
    long int i;
    *dest = IDENT;
    for (i = 0; i < vec_length(v); i++) {
        data_t val;
        get_vec_element(v, i, &val);
        *dest = *dest OP val;
    }
}
```

**Data Types**
- Use different declarations for `data_t`
  - `int`
  - `long`
  - `float`
  - `double`

**Operations**
- Use different definitions of `OP` and `IDENT`
  - `+ / 0`
  - `* / 1`

Compute sum or product of vector elements
Cycles Per Element (CPE)

- Convenient way to express performance of program that operates on vectors or lists
- Length = n
- In our case: CPE = cycles per OP
- T = CPE*n + Overhead
  - CPE is slope of line

![Graph showing Cycles vs. Elements]

- psum1: Slope = 9.0
- psum2: Slope = 6.0
Benchmark Performance

```c
void combine1(vec_ptr v, data_t *dest) {
    long int i;
    *dest = IDENT;
    for (i = 0; i < vec_length(v); i++) {
        data_t val;
        get_vec_element(v, i, &val);
        *dest = *dest OP val;
    }
}
```

Method | Integer | Double FP
--- | --- | ---
Operation | Add | Mult | Add | Mult
Combine1 unoptimized | 22.68 | 20.02 | 19.98 | 20.18
Combine1 –O1 | 10.12 | 10.12 | 10.17 | 11.14

Compute sum or product of vector elements
Basic Optimizations

void combine4(vec_ptr v, data_t *dest)
{
  long i;
  long length = vec_length(v);
  data_t *d = get_vec_start(v);
  data_t t = IDENT;
  for (i = 0; i < length; i++)
    t = t OP d[i];
  *dest = t;
}

- Move vec_length out of loop
- Avoid bounds check on each cycle
- Accumulate in temporary
Effect of Basic Optimizations

```c
void combine4(vec_ptr v, data_t *dest) {
    long i;
    long length = vec_length(v);
    data_t *d = get_vec_start(v);
    data_t t = IDENT;
    for (i = 0; i < length; i++)
        t = t OP d[i];
    *dest = t;
}
```

Superscalar Processor

- **Definition:** A superscalar processor can issue and execute *multiple instructions in one cycle*. The instructions are retrieved from a sequential instruction stream and are usually scheduled dynamically.

- **Benefit:** without programming effort, superscalar processor can take advantage of the *instruction level parallelism* that most programs have

- Most modern CPUs are superscalar.
- Intel: since Pentium (1993)
Pipelined Functional Units

```c
long mult_eg(long a, long b, long c) {
    long p1 = a*b;
    long p2 = a*c;
    long p3 = p1 * p2;
    return p3;
}
```

- Divide computation into stages
- Pass partial computations from stage to stage
- Stage i can start on new computation once values passed to i+1
- E.g., complete 3 multiplications in 7 cycles, even though each requires 3 cycles

<table>

</tbody>
</table>
Haswell CPU

- 8 Total Functional Units

- **Multiple instructions can execute in parallel**
  - 2 load, with address computation
  - 1 store, with address computation
  - 4 integer
  - 2 FP multiply
  - 1 FP add
  - 1 FP divide

- **Some instructions take > 1 cycle, but can be pipelined**

Combine4 = Serial Computation (OP = *)

- Computation (length=8)
  
  
  \[ (((((((1 * d[0]) * d[1]) * d[2]) * d[3]) * d[4]) * d[5]) * d[6]) * d[7]) \]

- Sequential dependence
  - Performance: determined by latency of OP
Loop Unrolling (2x1)

```c
void unroll2a_combine(vec_ptr v, data_t *dest)
{
    long length = vec_length(v);
    long limit = length-1;
    data_t *d = get_vec_start(v);
    data_t x = IDENT;
    long i;
    /* Combine 2 elements at a time */
    for (i = 0; i < limit; i+=2) {
        x = (x OP d[i]) OP d[i+1];
    }
    /* Finish any remaining elements */
    for (; i < length; i++) {
        x = x OP d[i];
    }
    *dest = x;
}
```

- Perform 2x more useful work per iteration
Effect of Loop Unrolling

<table>
<thead>
<tr>
<th>Method</th>
<th>Integer</th>
<th>Double FP</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operation</td>
<td>Add</td>
<td>Mult</td>

<td>1.01</td>
<td>3.01</td>
</tr>
<tr>
<td>Latency Bound</td>
<td>1.00</td>
<td>3.00</td>
</tr>
</tbody>
</table>

- Helps integer add
  - Achieves latency bound

- Others don’t improve. Why?
  - Still sequential dependency

\[ x = (x \text{ OP } d[i]) \text{ OP } d[i+1]; \]
Loop Unrolling with Reassociation (2x1a)

Can this change the result of the computation?
Yes, for FP. Why?
### Effect of Reassociation

<table>
<thead>
<tr>
<th>Method</th>
<th>Integer</th>
<th>Double FP</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Operation</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Combine4</td>
<td>1.27</td>
<td>3.01</td>
</tr>
<tr>
<td>Unroll 2x1</td>
<td>1.01</td>
<td>3.01</td>
</tr>
<tr>
<td>Unroll 2x1a</td>
<td>1.01</td>
<td>1.51</td>
</tr>
<tr>
<td><strong>Latency Bound</strong></td>
<td>1.00</td>
<td>3.00</td>
</tr>
<tr>
<td><strong>Throughput Bound</strong></td>
<td>0.50</td>
<td>1.00</td>
</tr>
</tbody>
</table>

- **Nearly 2x speedup for Int *, FP +, FP ***
  - Reason: Breaks sequential dependency
    
    \[ x = x \text{ OP} (d[i] \text{ OP} d[i+1]) \]

- Why is that? (next slide)

2 func. units for FP *
2 func. units for load

4 func. units for int +
2 func. units for load
Reassociated Computation

\[ x = x \text{ OP} (d[i] \text{ OP} d[i+1]); \]

- **What changed:**
  - Ops in the next iteration can be started early (no dependency)

- **Overall Performance**
  - N elements, D cycles latency/\(\text{op}\)
  - \((N/2+1)*D\) cycles:
    \[ \text{CPE} = D/2 \]
Loop Unrolling with Separate Accumulators (2x2)

```c
void unroll2a_combine(vec_ptr v, data_t *dest) {
    long length = vec_length(v);
    long limit = length-1;
    data_t *d = get_vec_start(v);
    data_t x0 = IDENT;
    data_t x1 = IDENT;
    long i;
    /* Combine 2 elements at a time */
    for (i = 0; i < limit; i+=2) {
        x0 = x0 OP d[i];
        x1 = x1 OP d[i+1];
    }
    /* Finish any remaining elements */
    for (; i < length; i++) {
        x0 = x0 OP d[i];
    }
    *dest = x0 OP x1;
}
```

- **Different form of reassociation**
## Effect of Separate Accumulators

<table>
<thead>
<tr>
<th>Method</th>
<th>Integer</th>
<th>Double FP</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Add</td>
<td>Mult</td>
</tr>
<tr>
<td>Combine4</td>
<td>1.27</td>
<td>3.01</td>
</tr>
<tr>
<td>Unroll 2x1</td>
<td>1.01</td>
<td>3.01</td>
</tr>
<tr>
<td>Unroll 2x1a</td>
<td>1.01</td>
<td>1.51</td>
</tr>
<tr>
<td>Unroll 2x2</td>
<td>0.81</td>
<td>1.51</td>
</tr>
<tr>
<td>Latency Bound</td>
<td>1.00</td>
<td>3.00</td>
</tr>
<tr>
<td>Throughput Bound</td>
<td>0.50</td>
<td>1.00</td>
</tr>
</tbody>
</table>

- **Int +** makes use of two load units
  - \(x_0 = x_0 \text{ OP } d[i] ;\)
  - \(x_1 = x_1 \text{ OP } d[i+1] ;\)

- 2x speedup (over unroll2) for Int *, FP +, FP *
Separate Accumulators

\[ x_0 = x_0 \text{ OP } d[i]; \]
\[ x_1 = x_1 \text{ OP } d[i+1]; \]

- **What changed:**
  - Two independent “streams” of operations

- **Overall Performance**
  - N elements, D cycles latency/op
  - Should be \((N/2+1)*D\) cycles:
    \[ \text{CPE} = D/2 \]
  - CPE matches prediction!

**What Now?**
Unrolling & Accumulating

■ Idea
  ▪ Can unroll to any degree L
  ▪ Can accumulate K results in parallel
  ▪ L must be multiple of K

■ Limitations
  ▪ Diminishing returns
    ▪ Cannot go beyond throughput limitations of execution units
  ▪ Large overhead for short lengths
    ▪ Finish off iterations sequentially
Unrolling & Accumulating: Double *

Case

- Intel Haswell
- Double FP Multiplication
- Latency bound: 5.00. Throughput bound: 0.50

<table>
<thead>
<tr>
<th>FP *</th>
<th>Unrolling Factor L</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>K 1 2 3 4 6 8 10 12</td>
</tr>
<tr>
<td></td>
<td>1 5.01 5.01 5.01 5.01 5.01 5.01 5.01</td>
</tr>
<tr>
<td></td>
<td>2 2.51 2.51 2.51</td>
</tr>
<tr>
<td></td>
<td>3 1.67</td>
</tr>
<tr>
<td></td>
<td>4 1.25 1.26</td>
</tr>
<tr>
<td></td>
<td>6 0.84 0.88</td>
</tr>
<tr>
<td></td>
<td>8 0.63</td>
</tr>
<tr>
<td></td>
<td>10 0.51</td>
</tr>
<tr>
<td></td>
<td>12 0.52</td>
</tr>
</tbody>
</table>
Unrolling & Accumulating: Int +

**Case**

- Intel Haswell
- Integer addition
- Latency bound: 1.00. Throughput bound: 1.00

<table>
<thead>
<tr>
<th>FP *</th>
<th>Unrolling Factor L</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>K</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>1.27</td>
</tr>
<tr>
<td>2</td>
<td>0.81</td>
</tr>
<tr>
<td>3</td>
<td>0.74</td>

<tr>
<td>10</td>
<td></td>
</tr>
<tr>
<td>12</td>
<td></td>
</tr>
</tbody>
</table>
### Achievable Performance

<table>
<thead>
<tr>
<th>Method</th>
<th>Integer</th>
<th>Double FP</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Add</td>
<td>Mult</td>
</tr>
<tr>
<td><strong>Operation</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Best</td>
<td>0.54</td>
<td>1.01</td>
</tr>
<tr>
<td>Latency Bound</td>
<td>1.00</td>
<td>3.00</td>
</tr>
<tr>
<td>Throughput Bound</td>
<td>0.50</td>
<td>1.00</td>
</tr>
</tbody>
</table>

- Limited only by throughput of functional units
- Up to 42X improvement over original, unoptimized code
## Programming with AVX2

### YMM Registers

- 16 total, each 32 bytes
- 32 single-byte integers
- 16 16-bit integers
- 8 32-bit integers
- 8 single-precision floats
- 4 double-precision floats
- 1 single-precision float
- 1 double-precision float
SIMD Operations

- **SIMD Operations: Single Precision**
  
  \[ \text{vaddsd} \ %\text{ymm0}, \ %\text{ymm1}, \ %\text{ymm1} \]

- **SIMD Operations: Double Precision**
  
  \[ \text{vaddpd} \ %\text{ymm0}, \ %\text{ymm1}, \ %\text{ymm1} \]
## Using Vector Instructions

<table>
<thead>
<tr>
<th>Method</th>
<th>Integer</th>
<th>Double FP</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Add</td>
<td>Mult</td>
</tr>
<tr>
<td>Operation</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Scalar Best</td>
<td>0.54</td>
<td>1.01</td>
</tr>
<tr>
<td>Vector Best</td>
<td>0.06</td>
<td>0.24</td>
</tr>
<tr>
<td>Latency Bound</td>
<td>0.50</td>
<td>3.00</td>
</tr>
<tr>
<td>Throughput Bound</td>
<td>0.50</td>
<td>1.00</td>
</tr>
<tr>
<td>Vec Throughput Bound</td>
<td>0.06</td>
<td>0.12</td>
</tr>
</tbody>
</table>

### Make use of AVX Instructions
- Parallel operations on multiple data elements
- See Web Aside OPT:SIMD on CS:APP web page
What About Branches?

- **Challenge**
  - Instruction Control Unit must work well ahead of Execution Unit to generate enough operations to keep EU busy

<table>
<thead>
<tr>
<th>Address</th>
<th>Opcode</th>
<th>Source/Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>404663:</td>
<td>mov</td>
<td>$0x0,%eax</td>
</tr>
<tr>
<td>404668:</td>
<td>cmp</td>
<td>(%rdi),%rsi</td>
</tr>
<tr>
<td>40466b:</td>
<td>jge</td>
<td>404685</td>
</tr>
<tr>
<td>40466d:</td>
<td>mov</td>
<td>0x8(%rdi),%rax</td>
</tr>
</tbody>
</table>

- When encounters conditional branch, cannot reliably determine where to continue fetching

```
404685: repz retq
```

Branch Outcomes

- When encounter conditional branch, cannot determine where to continue fetching
  - Branch Taken: Transfer control to branch target
  - Branch Not-Taken: Continue with next instruction in sequence
- Cannot resolve until outcome determined by branch/integer unit

```
404663: mov    $0x0,%eax
404668: cmp    (%rdi),%rsi
40466b: jge   404685
40466d: mov    0x8(%rdi),%rax
```

Branch Not-Taken

```
404685: repz retq
```

Branch Taken
Branch Prediction

- **Idea**
  - Guess which way branch will go
  - Begin executing instructions at predicted position
    - But don’t actually modify register or memory data

```
404663:   mov   $0x0,%eax
404668:   cmp   (%rdi),%rsi
40466b:   jge   404685
40466d:   mov   0x8(%rdi),%rax

...  
```

---

```
404685:  repz retq
```

---

**Predict Taken**

**Begin Execution**
Branch Prediction Through Loop

Assume
vector length = 100

```assembly
401029: vmulsd (%rdx),%xmm0,%xmm0
40102d: add $0x8,%rdx
401031: cmp %rax,%rdx
401034: jne 401029
```

\( i = 98 \)

Predict Taken (OK)

```
401029: vmulsd (%rdx),%xmm0,%xmm0
40102d: add $0x8,%rdx
401031: cmp %rax,%rdx
401034: jne 401029
```

\( i = 99 \)

Predict Taken (Oops)

```
401029: vmulsd (%rdx),%xmm0,%xmm0
40102d: add $0x8,%rdx
401031: cmp %rax,%rdx
401034: jne 401029
```

\( i = 100 \)

Read invalid location

```
401029: vmulsd (%rdx),%xmm0,%xmm0
40102d: add $0x8,%rdx
401031: cmp %rax,%rdx
401034: jne 401029
```

\( i = 101 \)

Executed

Fetched
Branch Misprediction Invalidation

```

\[ i = 99 \]

- **Definitely not taken**
- **Reload Pipeline**

**Performance Cost**
- Multiple clock cycles on modern processor
- Can be a major performance limiter
Getting High Performance

- Good compiler and flags
- Don’t do anything stupid
  - Watch out for hidden algorithmic inefficiencies
  - Write compiler-friendly code
    - Watch out for optimization blockers: procedure calls & memory references
  - Look carefully at innermost loops (where most work is done)

- Tune code for machine
  - Exploit instruction-level parallelism
  - Avoid unpredictable branches
  - Make code cache friendly (Covered later in course)
