
Anita's Super Awesome Recitation slides

15/18-213: Introduction to Computer Systems
More Shell and Virtual Memory, 2 July2013

Anita Zhang, Section M

Boring Stuff

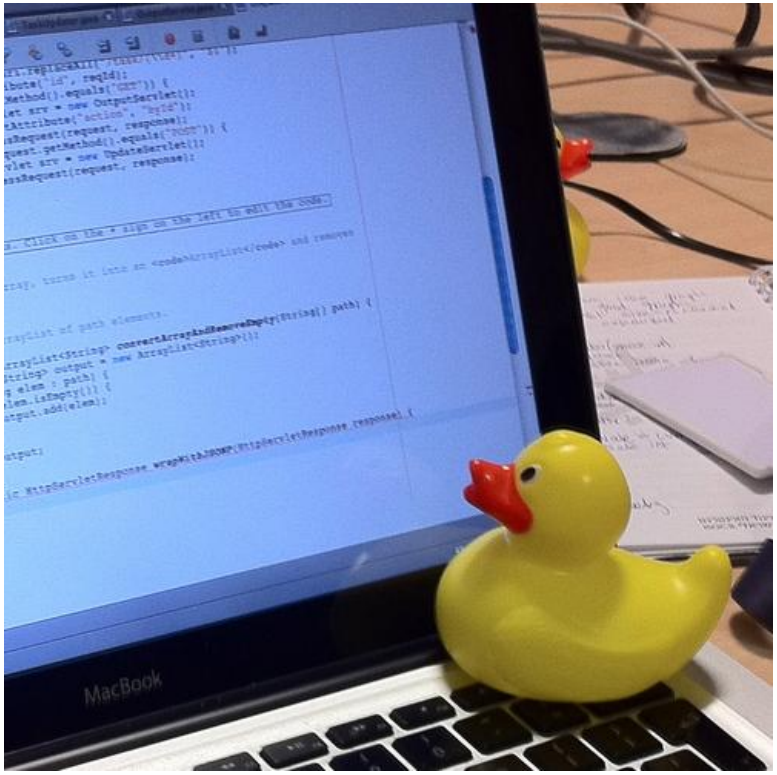
- Shell Lab due next Tuesday, 9 July 2013
  - Your first concurrency assignment!
  - If you like process level concurrency, take OS ☺
- Malloc Lab out the same time Shell Lab is due
  - My favorite lab!
  - Design and implement a memory allocator
- Pressing concerns?

Menu for Today

- Advice, not Motivation
- The Rest of Shell Lab
  - I/O (with Pictures!)
  - How to sigsuspend()
  - Minor Details
- Virtual Memory
- Address Translation
- Extra: C Primer

Rubber Duck Debugging

"To use this process, a programmer explains code to an inanimate object, such as a rubber duck, with the expectation that upon reaching a piece of incorrect code and trying to explain it, the programmer will notice the error."



More on Ducks

I/O

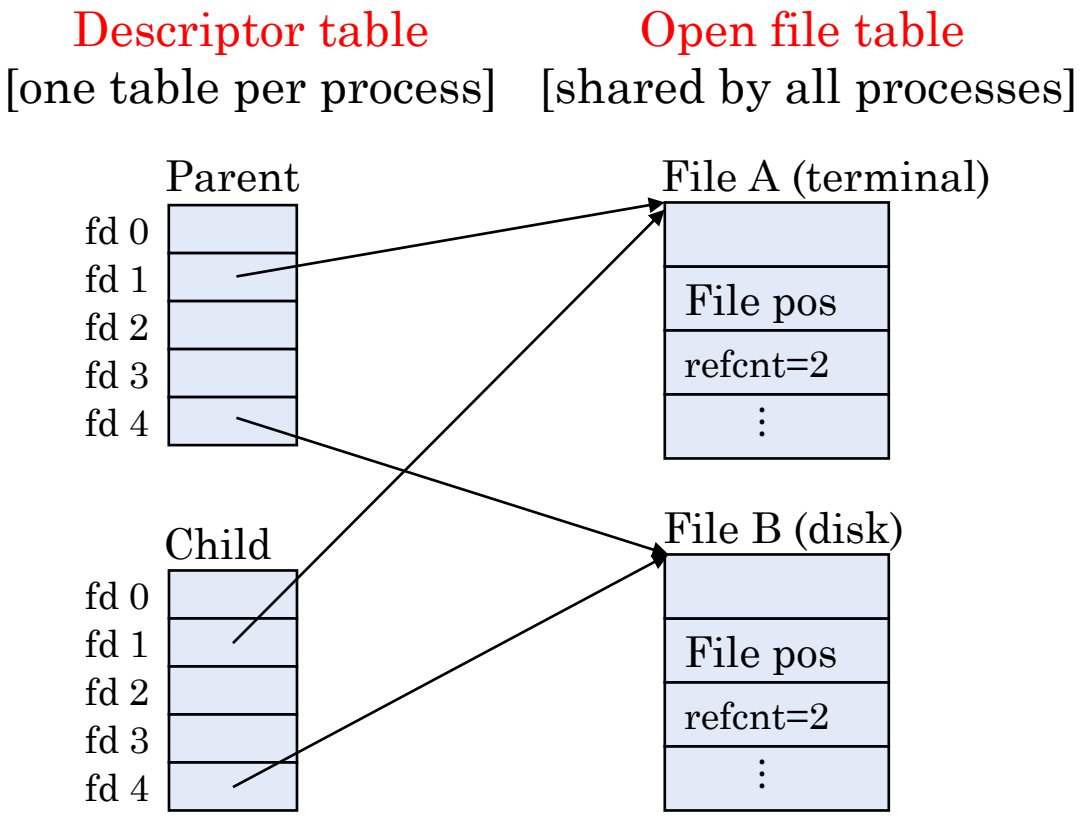
- Four basic operations
  - open()
  - close()
  - read()
  - write()
- What's a file descriptor?
  - Returned by `open()`
  - Some positive value, or -1 to denote error
  - `int fd = open("/path/to/file", O_RDONLY);`

File Descriptors

- Every process starts with these 3 by default
  - 0 – STDIN
  - 1 – STDOUT
  - 2 – STDERR
- Every process gets its own **file descriptor table**
  - Used to refer to the opened files
- Forked processes share open file tables

Parent and Child After fork()

- Shamelessly stolen from lecture:

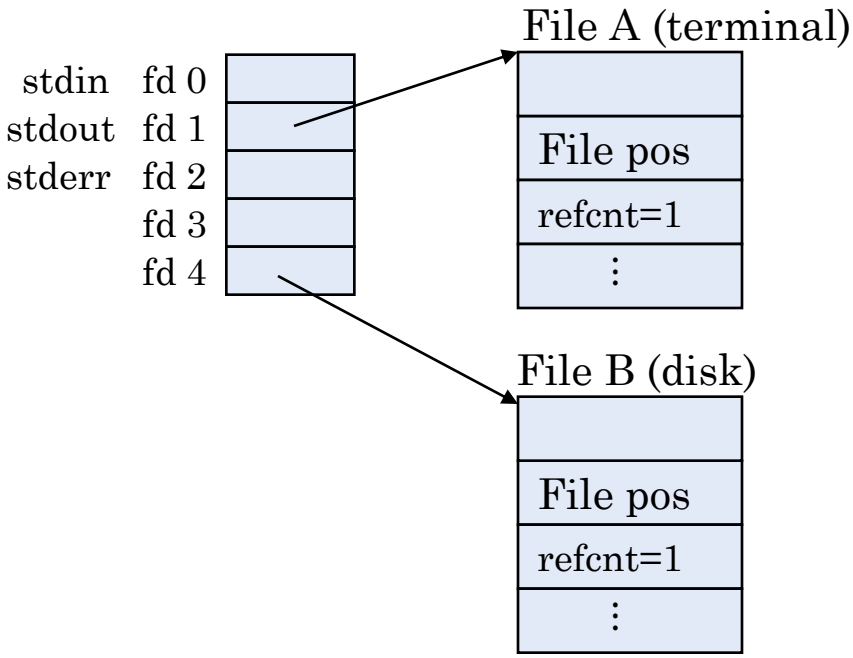


What is dup2()?

- Copies file descriptor entries
  - Causes the entries to point to the same files as another file descriptor
- Takes the form: `dup2(dest_fd, src_fd)`
  - `src_fd` will now point to the same place as `dest_fd`

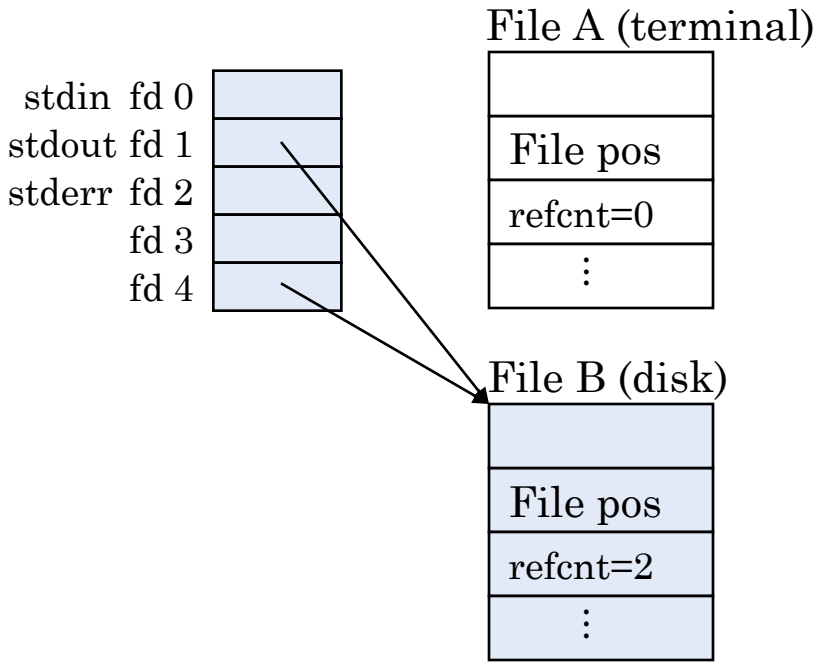
DUP2() SUPER RELEVANT: BEFORE

- Goal: Redirect stdout
- First, use `open()` to open a file to redirect
  - For Shell Lab: Done right before the call to `exec()` in the child process
  - This example, fd 4 is the file descriptor of the opened file



dup2() Super Relevant: After

- To redirect, duplicate fd 4 into fd 1.
- Call `dup2(4, 1)`
  - Causes fd 1 to refer to disk file pointed at by fd 4
- Accessing fd 1 will now get you File B



SIGSUSPEND() BACKGROUND

- What is `sigsuspend()`?
  - Used to protect critical regions from signal interruption.
  - It is especially useful for (you guessed it) "pausing" or "sleeping" while waiting for a signal.
  - Much better solution to the "sleep loop"
- Goal: to block all the way up until the instruction our process is suspended.

SIGSUSPEND() DETAILS

- `int sigsuspend(const sigset_t *sigmask);`
  - Where `sigmask` contains a mask of signals YOU DON'T want to be interrupted by
  - Can be considered opposite of `sigprocmask()` which takes a mask of signals you want to operate on.
- Quick example: if you want to be woken up from `sigsuspend()` by SIGCHLD, it better not be in the mask you pass in!

How to sigsuspend()

```
int main() {
    sigset_t waitmask, newmask, oldmask;

    /* set with everything except SIGINT */
    sigfillset(&waitmask);
    sigdelset(&waitmask, SIGINT);

    /* set with only SIGINT */
    sigemptyset(&newmask);
    sigaddset(&newmask, SIGINT);

    /* oldmask contains the mask of signals before the
     * block with newmask */
    if (sigprocmask(SIG_BLOCK, &newmask, &oldmask) < 0)
        unix_error("SIG_BLOCK error");

    /* "CRITICAL REGION OF CODE" - (SIGINT blocked) */

    /* Pause, allowing ONLY SIGINT */
    if (sigsuspend(&waitmask) != -1)
        unix_error("sigsuspend error");

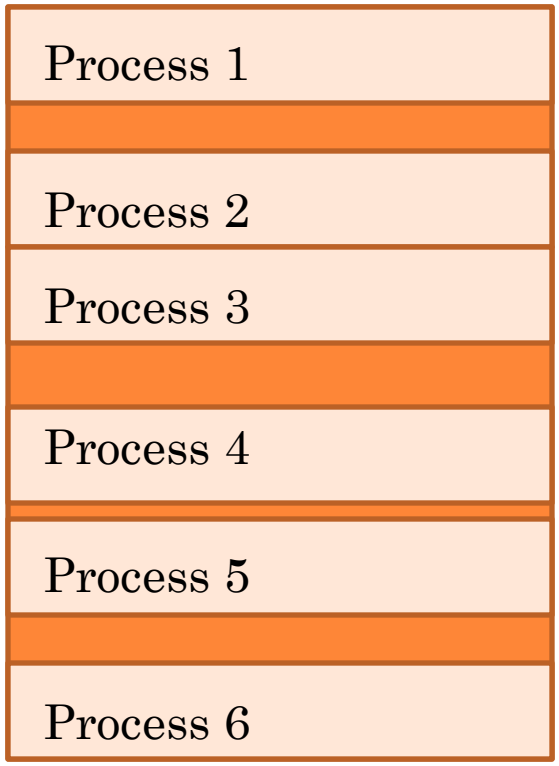
    /* RETURN FROM SIGSUSPEND -- (Returns to signal
     * state from before sigsuspend) */
    /* Reset signal mask which unblocks SIGINT */
    if (sigprocmask(SIG_SETMASK, &oldmask, NULL) < 0)
        unix_error("SIG_SETMASK error");
}
```

- Points of interest
  - `Sigprocmask()` fills oldmask with the signal mask from before SIG_BLOCK
  - If `sigsuspend()` returns from being awoken, it returns 1.
  - After `sigsuspend()` returns, the state of the signals returns to how it was before the call

VM: Problems with Direct Mapping

- Questions to ponder:
  - How can we grow processes safely?
  - What to do about fragmentation?
  - How can we make large contiguous chunks fit easier?

Direct Mapping Fragmentation



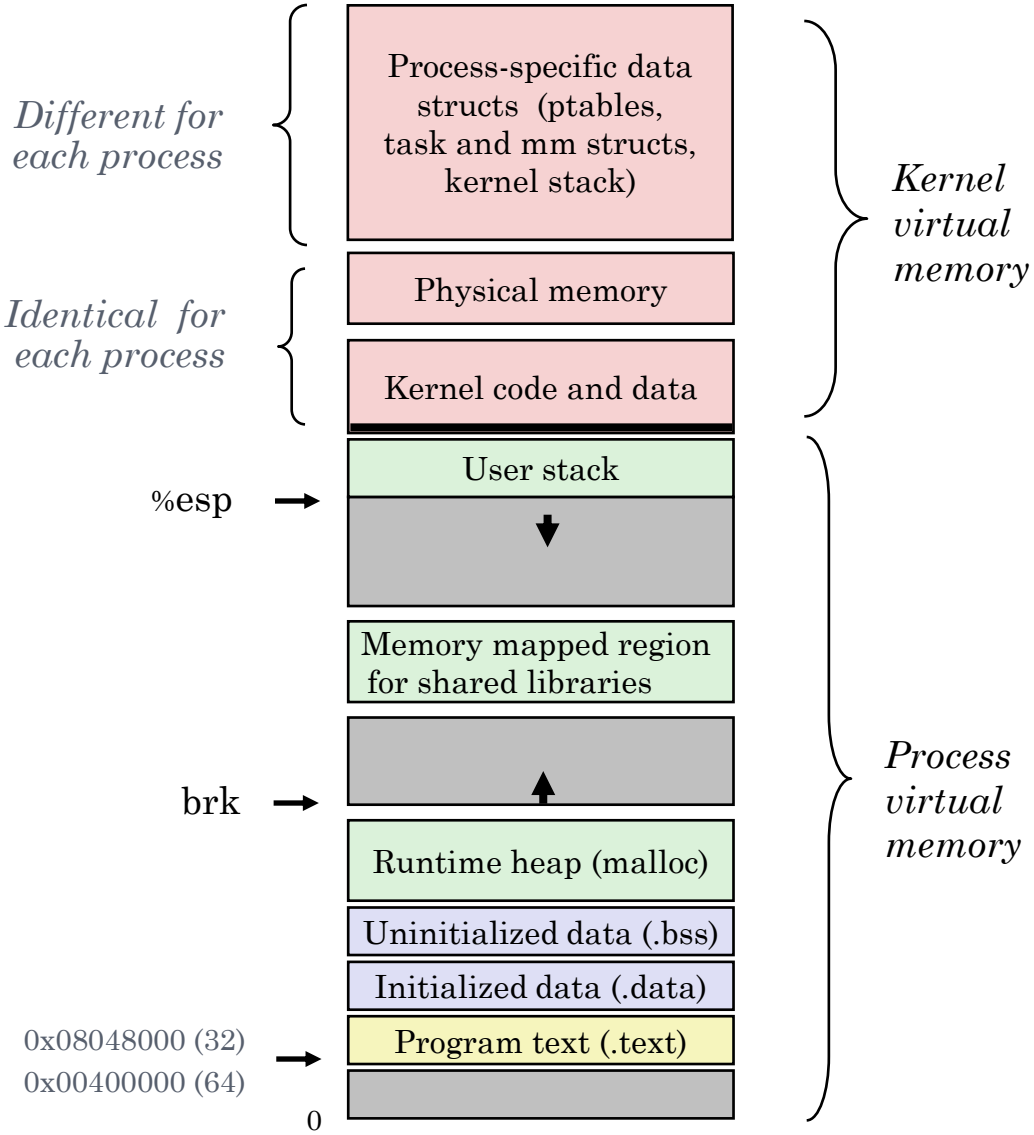
How do we Solve These Problems?

- We are scientists (and engineers)…
  - Insert a level of indirection

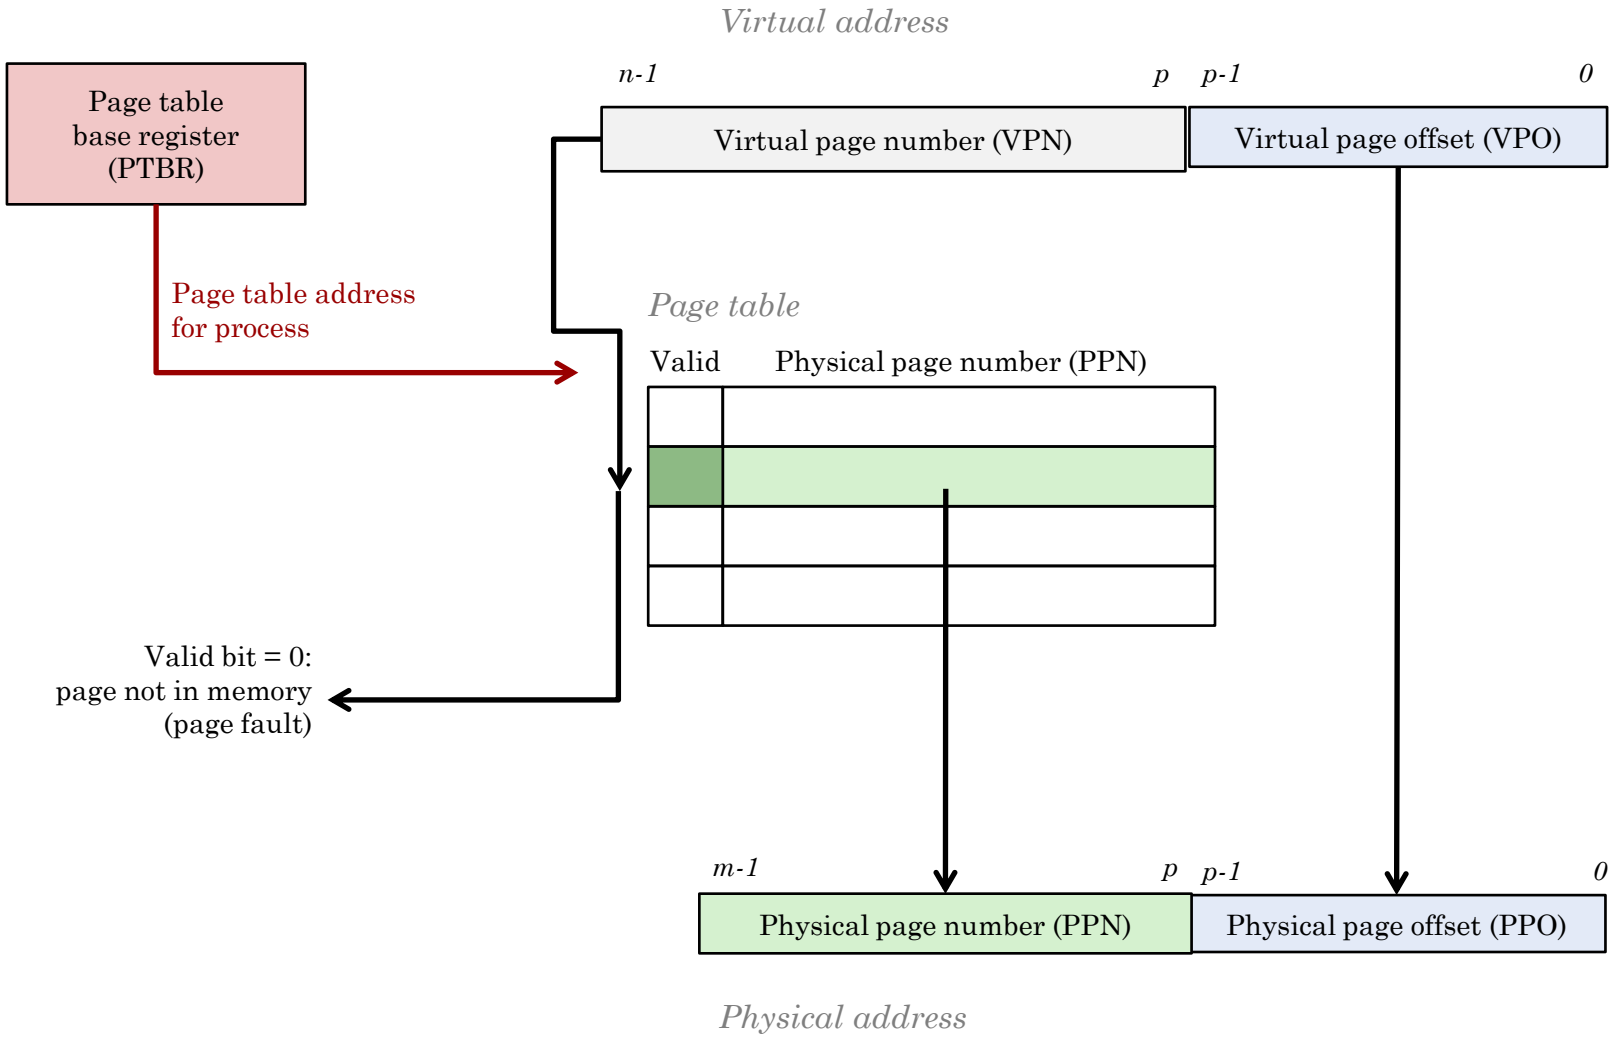
Virtual Memory

- ..Is the Best Thing Ever™
  - Demand paging
  - Memory Management
  - Protection
- Allows the illusion of infinite memory
  - Kernel manages page faults
- Each process gets its own virtual address space
  - Mapping is the heart of virtual memory

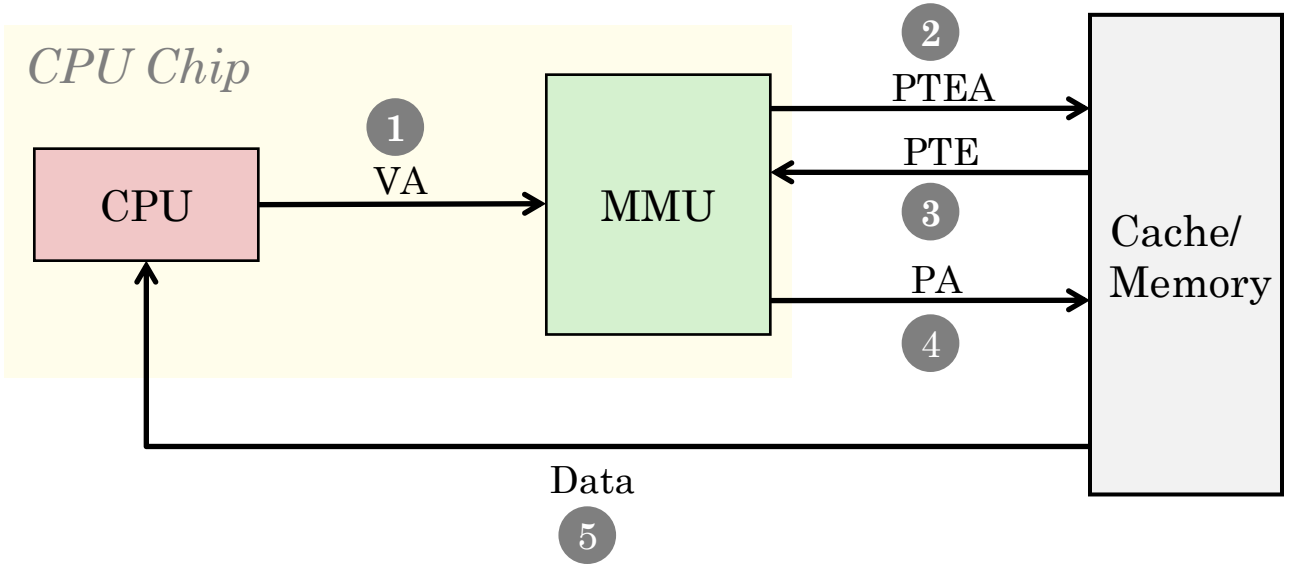
VM of a Linux Process



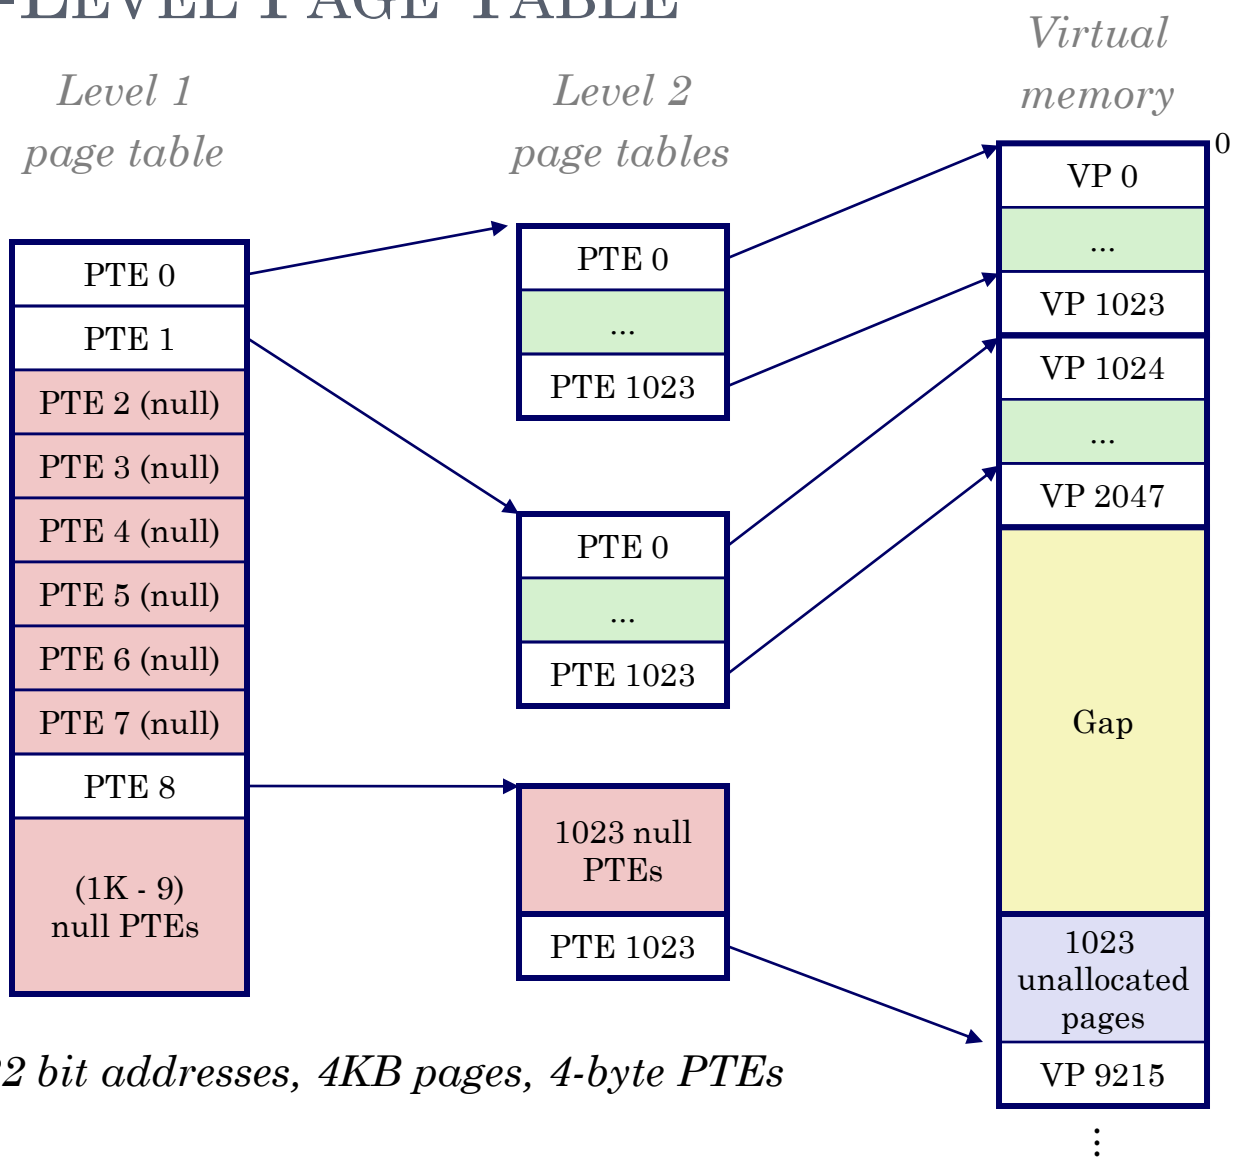
VM: Address Translations



Overview of a Hit

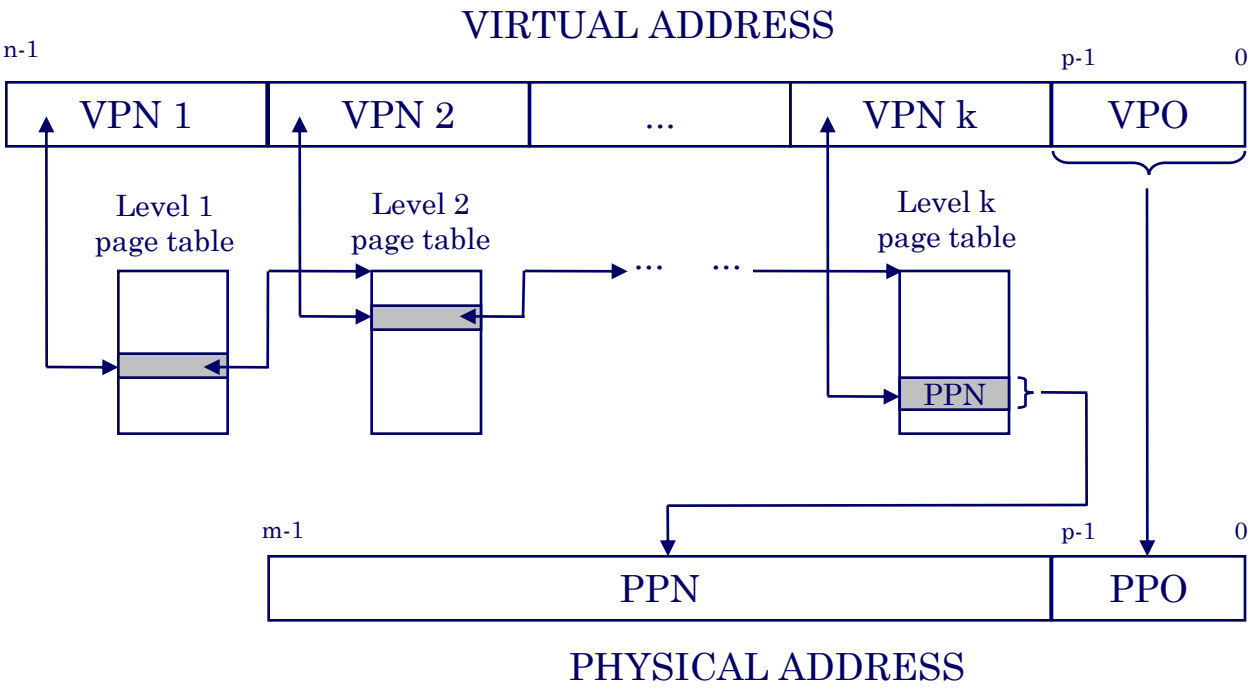


Two-Level Page Table



32 bit addresses, 4KB pages, 4-byte PTEs

Translating w/ a k-level Page Table



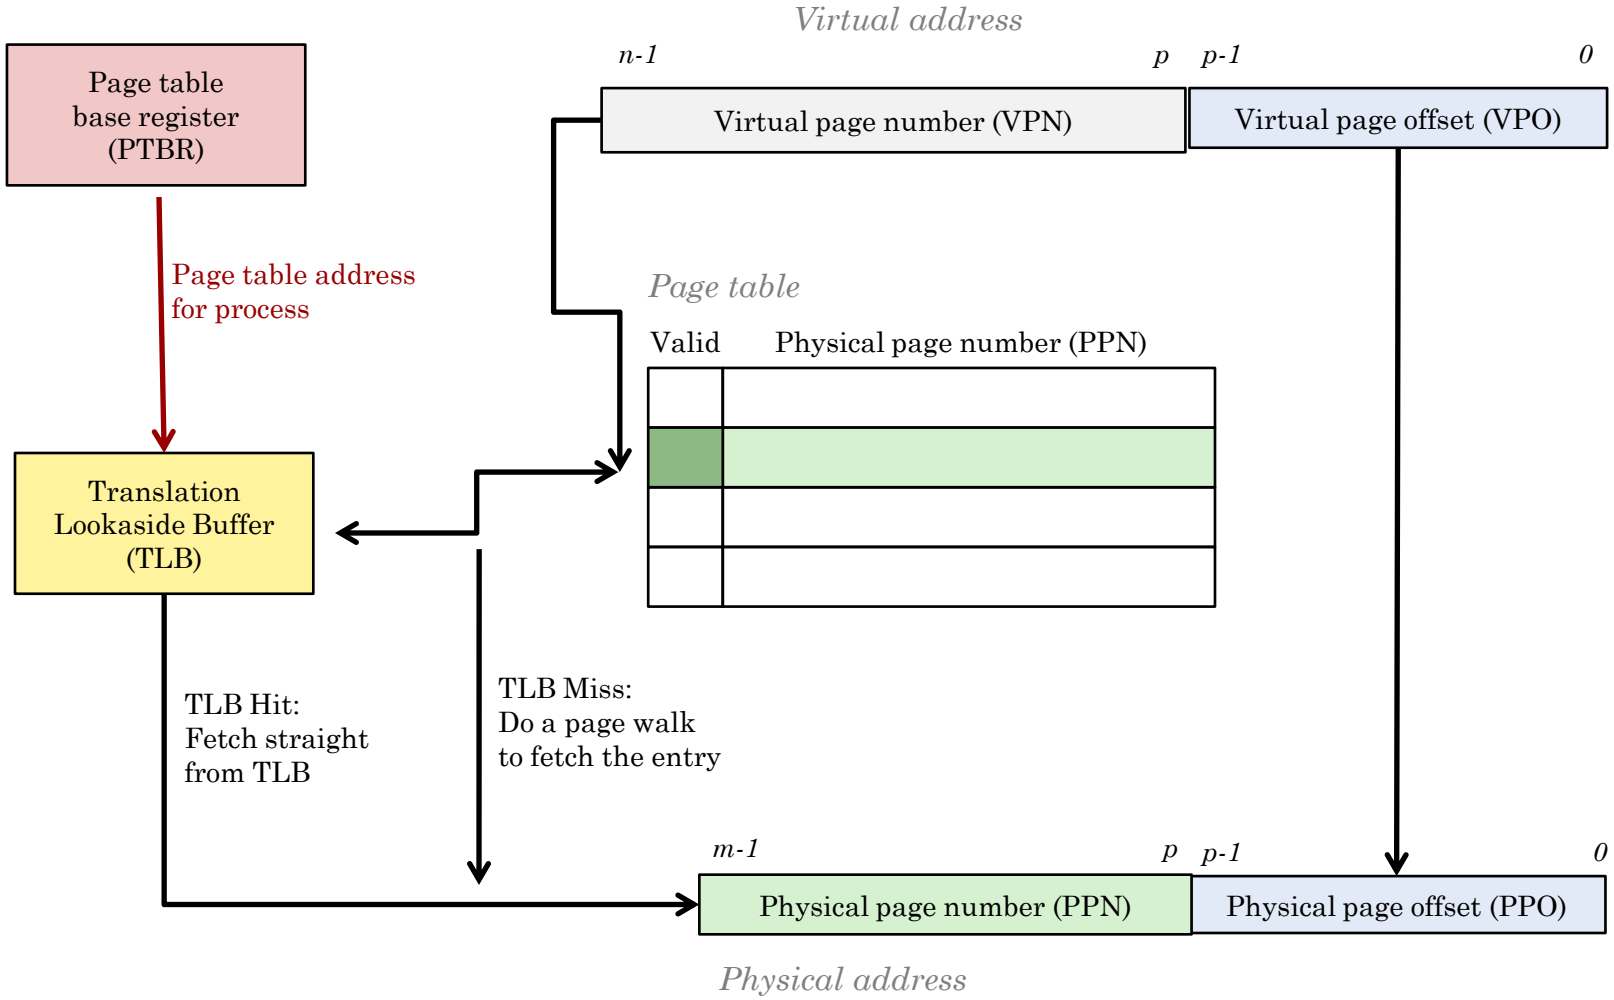
But Memory Accesses are Slow

- At least 2 memory accesses
  - Fetch page-table entry (PTE) from memory
  - Then fetch data from memory
- In x86, 3 memory accesses
  - Page directory, page table, physical memory
- In x86_64, 4 level page-mapping system
- What should we do?
  - Please don't say insert a level of "indirection"

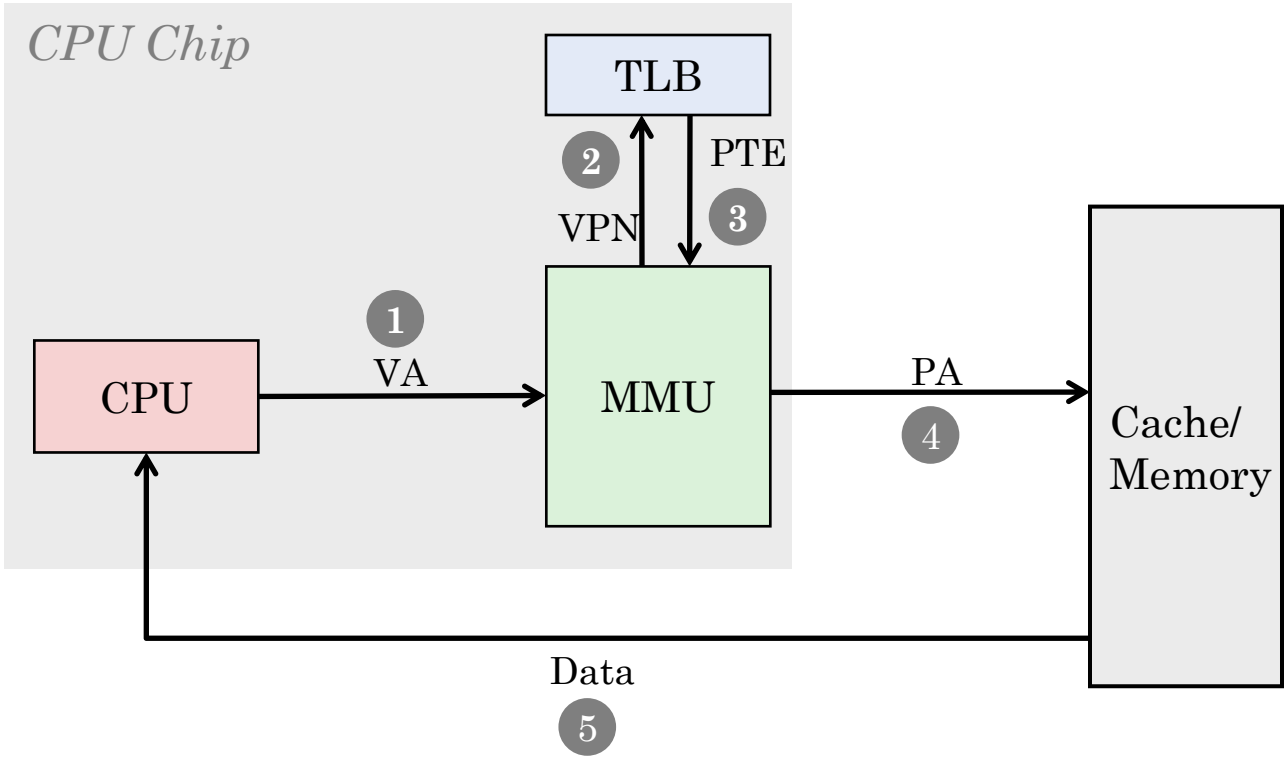
Translation Lookaside Buffer (TLB)

- Super fast hardware cache of PTEs
- Idea: Locality exists between memory accesses
  - Typically access nearby memory
  - Usually on the same page as current data
    - Arrays with loops
    - Program instructions

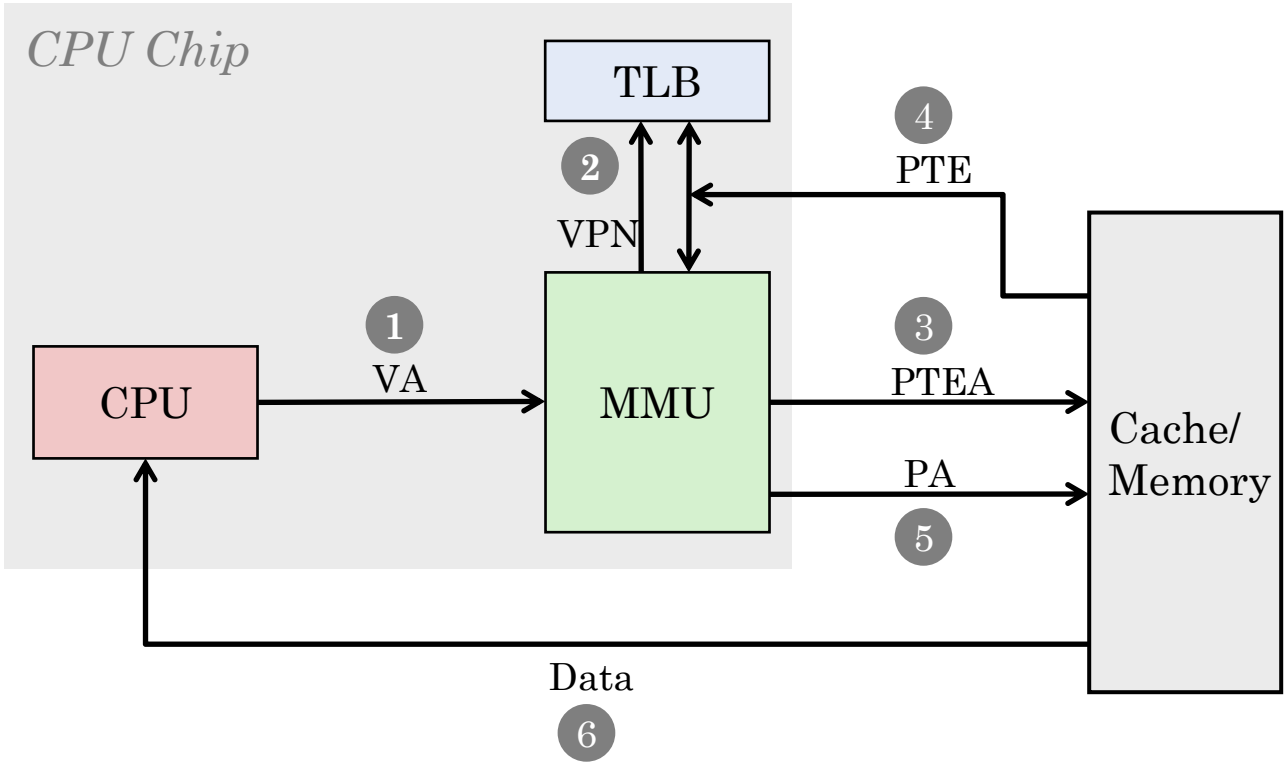
VM: Translations w/ TLB and Tables



Overview of a TLB Hit



Overview of a TLB Miss



Tutorial: Virtual Address Translation

- Addressing
  - 32 bit virtual address
  - 32 bit physical address
  - Page size = 4 kb
- Paging
  - 10 bit page directory index
  - 10 bit page table index
  - 12 bit offset
- TLB
  - Direct Mapped
  - 4 entries

Tutorial: Address Translation Miss

Translation Macro Exercise

- 32 bit address: 10 bit VPN1, 10 bit VPN2, 12 bit VPO
- 4KB pages
- Define the following function like macros:
  - Page align

```
#define PAGE_ALIGN(v_addr) _____________________________________
```

  - Gets VPN1/VPN2 as unsigned int from virtual address

```
#define VPN1(v_addr) _____________________________________
#define VPN2(v_addr) _____________________________________
```

  - Gets VPO as unsigned int from virtual address

```
#define VPO(v_addr) _____________________________________
```

  - Calculates the address of the page directory index

```
#define PDEA(pd_addr, v_addr) _____________________________________
```

  - Calculate address of page table entry

```
#define PTEA(pd_addr, v_addr)_____________________________________
```

  - Calculate physical address

```
#define PA(pd_addr, v_addr) _____________________________________
```

Translation Macro Solution

- 32 bit address: 10 bit VPN1, 10 bit VPN2, 12 bit VPO
- 4KB pages
- Define the following function like macros:
  - Page align

```
#define PAGE_ALIGN(v_addr) ((unsigned int) v_addr & ~0xfff)
```

  - Gets VPN1/VPN2 as unsigned int from virtual address

```
#define VPN1(v_addr) ((unsigned int) (((v_addr)>>22)&0x3ff))
#define VPN2(v_addr) ((unsigned int) (((v_addr)>>12)&0x3ff))
```

  - Gets VPO as unsigned int from virtual address

```
#define VPO(v_addr) ((unsigned int) ((v_addr)&0xfff))
```

  - Calculates the address of the page directory index

```
#define PDEA(pd_addr, v_addr) (((void **)pd_addr)+VPN1(v_addr))
```

  - Calculate address of page table entry

```
#define PTEA(pd_addr, v_addr)
     (((void **)PAGE_ALIGN(*PDEA(pd_addr,v_addr)))+VPN2(v_addr))
```

  - Calculate physical address

```
#define PA(pd_addr, v_addr)
     (((PAGE_ALIGN(*PTEA(pd_addr,v_addr)))) | VPO(v_addr))
```

Extra Stuff

- For next week, or for your enjoyment

All the C!

- "Saving you from malloc misery…"
- Basics
- Useful C Stuff
- Debugging
- Brian W. Kernighan and Dennis M. Ritchie, *The C Programming Language, Second Edition,* Prentice Hall, 1988

C and Pointer Basics

- Statically allocated arrays:
  - `int prices[100];`
  - Get rid of magic numbers:
    - `int prices[NUMITEMS];`
- Dynamically allocated arrays:
  - `int *prices2 = (int *) malloc(sizeof(int) * var);`
- Which is valid:
  - `prices2 = prices;`
  - `prices = prices2;`
- The & operator:
  - `&prices[1]` is the same as `prices+1`
- Function Pointer:
  - `int (*fun)();`
  - Pointer to function returning int

Peeling the Onion (K&R p.101)

- `char **argv`
  - argv: pointer to a pointer to a char
- `int (*daytab)[13]`
  - daytab: pointer to array[13] of int
- `int *daytab[13]`
  - daytab: array[13] of pointer to int
- `char (*(*x())[])()`
  - x: function returning pointer to array[] of pointer to function returning char
- `char (*(*x[3])())[5]`
  - x: array[3] of pointer to function returning pointer to array[5] of char
- Takeaway
  - There is an algorithm to decode this (see K&R p. 101)
  - Always use parenthesis!!

Why Typedefs?

- For convenience and readable code
- Example:
  - ```
    typedef struct
    {
       int x;
       int y;
    } point;
    ```
- Function Pointer example:
  - `typedef int(*pt2Func)(int, int);`
  - `pt2Func` is a pointer to a function that takes 2 int arguments and returns an int

    ```

Macros are Cool

- C Preprocessor looks at macros during the preprocessing step of compilation
- Use `#define` to avoid magic numbers:
  - `#define TRIALS 100`
- Function like macros – short and heavily used code snippets
  - `#define GET_BYTE_ONE(x) ((x) & 0xff)`
  - `#define GET_BYTE_TWO(x) ( ( (x) >> 8) & 0xff)`
- Also look at inline functions (example prototype):
  - `inline int max(int a, int b)`
  - Requests compiler to insert assembly of max wherever a call to max is made
- Both useful for malloc lab

Debugging – Favorite Methods

- Using the `DEBUG` flag:
  - #define DEBUG

    #ifdef DEBUG
    #define dbg_printf(...) printf(__VA_ARGS__)
    #else
    #define dbg_printf(...)
    #endif
- Compiling (if you want to debug):
  - `gcc -DDEBUG foo.c -o foo`
- Using `assert`
  - `assert(posvar > 0);`
  - `man 3 assert`
- Compiling (if you want to turn off asserts):
  - `gcc -DNDEBUG foo.c -o foo`

Little Things

- Usage messages
  - Putting this in is a good habit – allows you to add features while keeping the user up to date
  - `man -h`
- `fopen/fclose`
  - Always error check!
- malloc()
  - Error check
  - Free everything you allocate
- Global variables
  - Namespace pollution
  - If you must, make them private:
    - `static int foo;`
