System-Level I/O

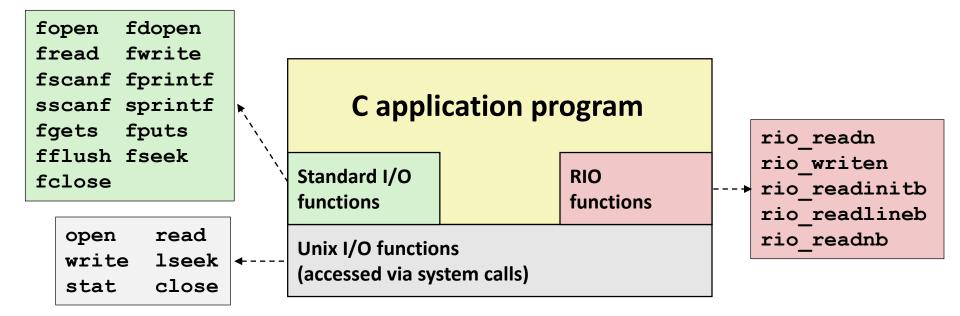

15-213: Introduction to Computer Systems 16th Lecture, June 22nd, 2016

Instructor:

Brian Railing

Today: Unix I/O and C Standard I/O

- Two sets: system-level and C level
- Robust I/O (RIO): 15-213 special wrappers good coding practice: handles error checking, signals, and "short counts"

Today

Unix I/O

- Metadata, sharing, and redirection
- RIO (robust I/O) package
- Standard I/O
- Closing remarks

Unix I/O Overview

- A Linux *file* is a sequence of *m* bytes:
 - $B_0, B_1, \dots, B_k, \dots, B_{m-1}$

Cool fact: All I/O devices are represented as files:

- /dev/sda2 (/usr disk partition)
- /dev/tty2 (terminal)

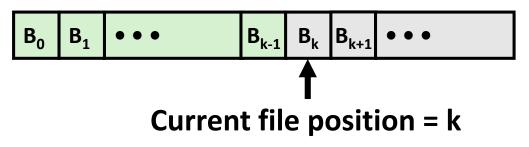

Even the kernel is represented as a file:

- /boot/vmlinuz-3.13.0-55-generic (kernel image)
- /proc (kernel data structures)

Unix I/O Overview

Elegant mapping of files to devices allows kernel to export simple interface called *Unix I/O*:

- Opening and closing files
 - open() and close()
- Reading and writing a file
 - read() and write()
- Changing the *current file position* (seek)
 - indicates next offset into file to read or write
 - lseek()

File Types

Each file has a *type* indicating its role in the system

- *Regular file:* Contains arbitrary data
- *Directory:* Index for a related group of files
- *Socket:* For communicating with a process on another machine

Other file types beyond our scope

- Named pipes (FIFOs)
- Symbolic links
- Character and block devices

Regular Files

- A regular file contains arbitrary data
- Applications often distinguish between text files and binary files
 - Text files are regular files with only ASCII or Unicode characters
 - Binary files are everything else
 - e.g., object files, JPEG images
 - Kernel doesn't know the difference!
- Text file is sequence of text lines
 - Text line is sequence of chars terminated by newline char ('\n')
 - Newline is **0xa**, same as ASCII line feed character (LF)
- End of line (EOL) indicators in other systems
 - Linux and Mac OS: '\n' (0xa)
 - line feed (LF)
 - Windows and Internet protocols: '\r\n' (0xd 0xa)
 - Carriage return (CR) followed by line feed (LF)

Directories

Directory consists of an array of *links*

• Each link maps a *filenam*e to a file

Each directory contains at least two entries

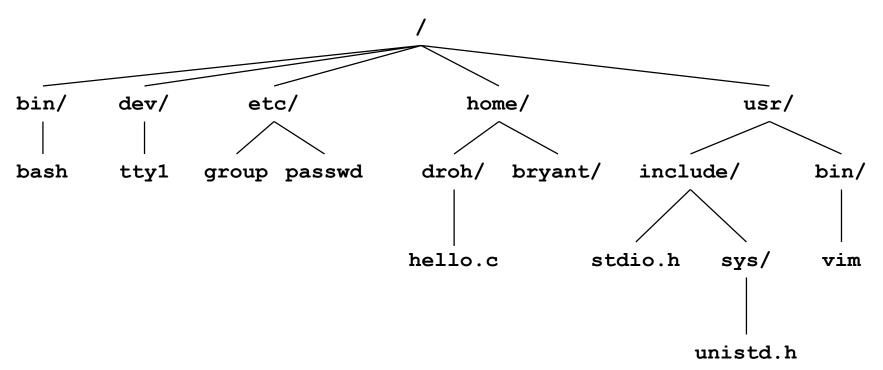

- . (dot) is a link to itself
- . (dot dot) is a link to the parent directory in the directory hierarchy (next slide)

Commands for manipulating directories

- mkdir: create empty directory
- ls: view directory contents
- **rmdir**: delete empty directory

Directory Hierarchy

 All files are organized as a hierarchy anchored by root directory named / (slash)

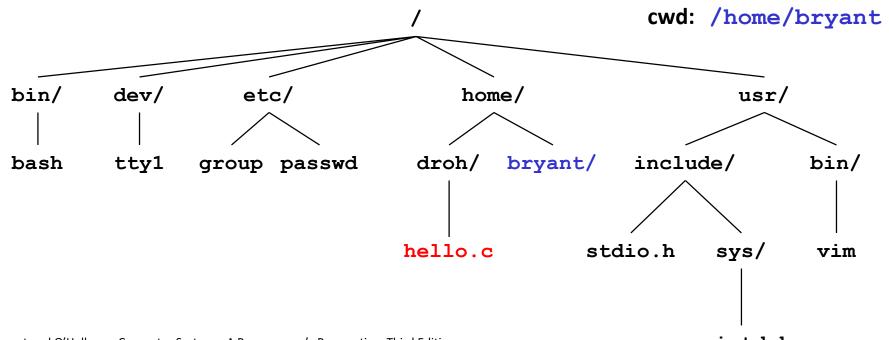

Kernel maintains current working directory (cwd) for each process

Modified using the cd command

Pathnames

Locations of files in the hierarchy denoted by *pathnames*

- Absolute pathname starts with '/' and denotes path from root
 - /home/droh/hello.c
- *Relative pathname* denotes path from current working directory
 - ../home/droh/hello.c

Opening Files

Opening a file informs the kernel that you are getting ready to access that file

```
int fd; /* file descriptor */
if ((fd = open("/etc/hosts", O_RDONLY)) < 0) {
    perror("open");
    exit(1);
}</pre>
```

Returns a small identifying integer *file descriptor*

- fd == -1 indicates that an error occurred
- Each process created by a Linux shell begins life with three open files associated with a terminal:
 - 0: standard input (stdin)
 - 1: standard output (stdout)
 - 2: standard error (stderr)

Closing Files

Closing a file informs the kernel that you are finished accessing that file

```
int fd;  /* file descriptor */
int retval; /* return value */
if ((retval = close(fd)) < 0) {
    perror("close");
    exit(1);
}</pre>
```

- Closing an already closed file is a recipe for disaster in threaded programs (more on this later)
- Moral: Always check return codes, even for seemingly benign functions such as close()

Reading Files

 Reading a file copies bytes from the current file position to memory, and then updates file position

Returns number of bytes read from file fd into buf

- Return type ssize_t is signed integer
- nbytes < 0 indicates that an error occurred</p>
- Short counts (nbytes < sizeof(buf)) are possible and are not errors!</p>

Writing Files

Writing a file copies bytes from memory to the current file position, and then updates current file position

Returns number of bytes written from buf to file fd

- nbytes < 0 indicates that an error occurred</p>
- As with reads, short counts are possible and are not errors!

Simple Unix I/O example

• Copying stdin to stdout, one byte at a time

```
#include "csapp.h"
int main(void)
{
    char c;
    while(Read(STDIN_FILENO, &c, 1) != 0)
        Write(STDOUT_FILENO, &c, 1);
        exit(0);
}
```

On Short Counts

Short counts can occur in these situations:

- Encountering (end-of-file) EOF on reads
- Reading text lines from a terminal
- Reading and writing network sockets

Short counts never occur in these situations:

- Reading from disk files (except for EOF)
- Writing to disk files

Best practice is to always allow for short counts.

Today

Unix I/O

- Metadata, sharing, and redirection
- RIO (robust I/O) package
- Standard I/O
- Closing remarks

File Metadata

Metadata is data about data, in this case file data

Per-file metadata maintained by kernel

accessed by users with the stat and fstat functions

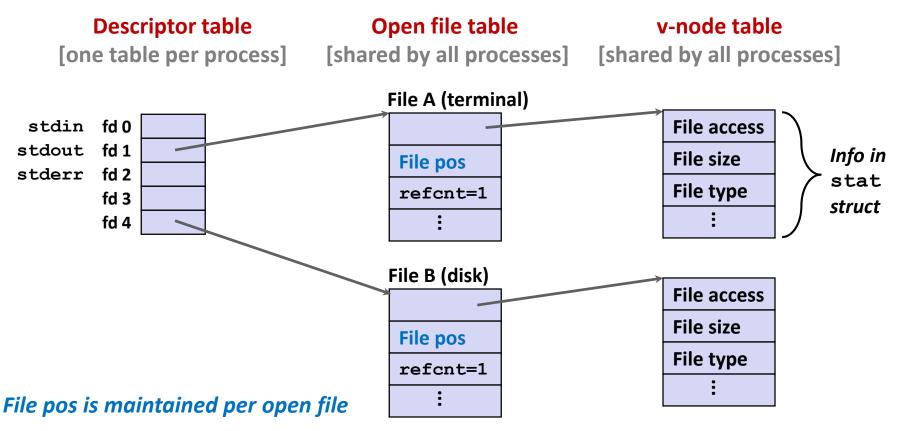

```
/* Metadata returned by the stat and fstat functions */
struct stat {
             st dev; /* Device */
   dev t
               st ino; /* inode */
   ino t
              st_mode; /* Protection and file type */
   mode t
   nlink_t st_nlink; /* Number of hard links */
               st uid; /* User ID of owner */
   uid t
               st_gid; /* Group ID of owner */
   gid t
   dev t st rdev; /* Device type (if inode device) */
               st size; /* Total size, in bytes */
   off t
   unsigned long st blksize; /* Blocksize for filesystem I/O */
   unsigned long st blocks; /* Number of blocks allocated */
   time t
        st atime; /* Time of last access */
   time t st mtime; /* Time of last modification */
   time t
              st ctime; /* Time of last change */
};
```

Example of Accessing File Metadata

```
linux> ./statcheck statcheck.c
int main (int argc, char **argv)
                                       type: regular, read: yes
                                       linux> chmod 000 statcheck.c
{
    struct stat stat;
                                       linux> ./statcheck statcheck.c
    char *type, *readok;
                                      type: regular, read: no
                                      linux> ./statcheck ..
    Stat(argv[1], &stat);
                                      type: directory, read: yes
    if (S ISREG(stat.st mode)) /* Determine file type */
       type = "regular";
    else if (S ISDIR(stat.st mode))
       type = "directory";
    else
       type = "other";
    if ((stat.st mode & S IRUSR)) /* Check read access */
       readok = "yes";
   else
        readok = "no";
   printf("type: %s, read: %s\n", type, readok);
   exit(0);
                                                     statcheck.c
```

How the Unix Kernel Represents Open Files

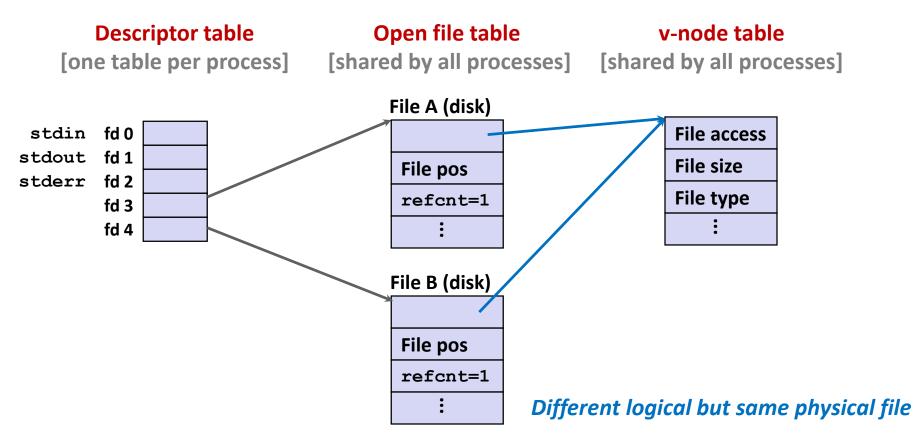

Two descriptors referencing two distinct open files. Descriptor 1 (stdout) points to terminal, and descriptor 4 points to open disk file

File Sharing

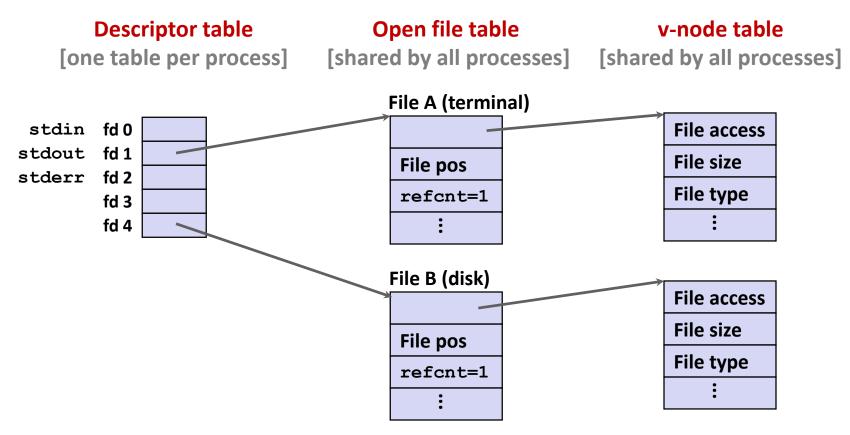

Two distinct descriptors sharing the same disk file through two distinct open file table entries

E.g., Calling open twice with the same filename argument

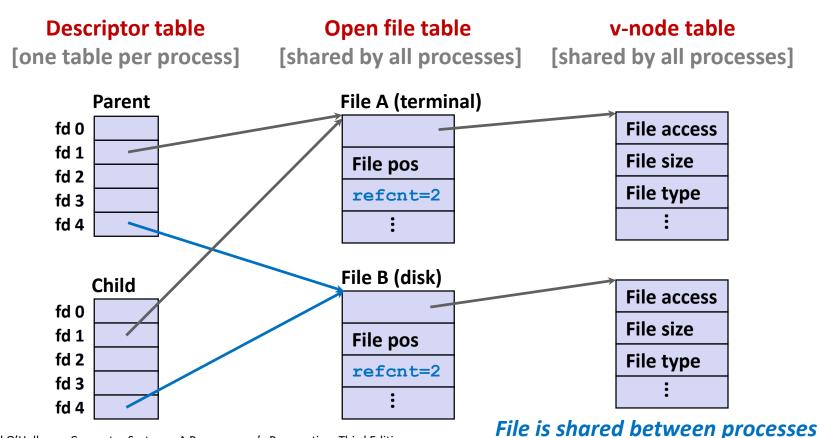

How Processes Share Files: fork

- A child process inherits its parent's open files
 - Note: situation unchanged by exec functions (use fcntl to change)
- Before fork call:

How Processes Share Files: fork

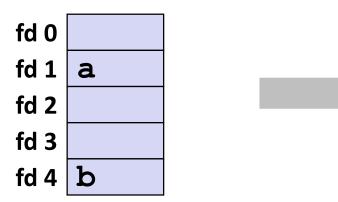

- A child process inherits its parent's open files
- After fork:
 - Child's table same as parent's, and +1 to each refcnt

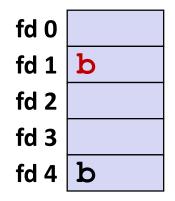

I/O Redirection

- Question: How does a shell implement I/O redirection? linux> ls > foo.txt
- Answer: By calling the dup2 (oldfd, newfd) function
 - Copies (per-process) descriptor table entry oldfd to entry newfd

Descriptor table *before* dup2 (4,1)

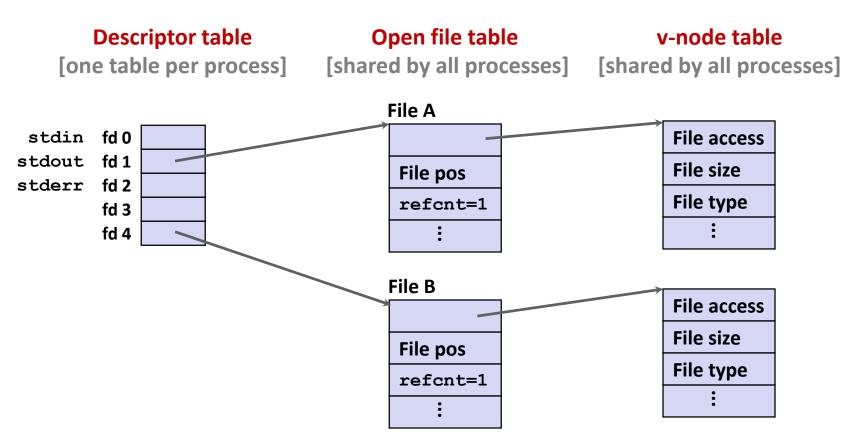

Descriptor table *after* dup2 (4,1)

I/O Redirection Example

Step #1: open file to which stdout should be redirected

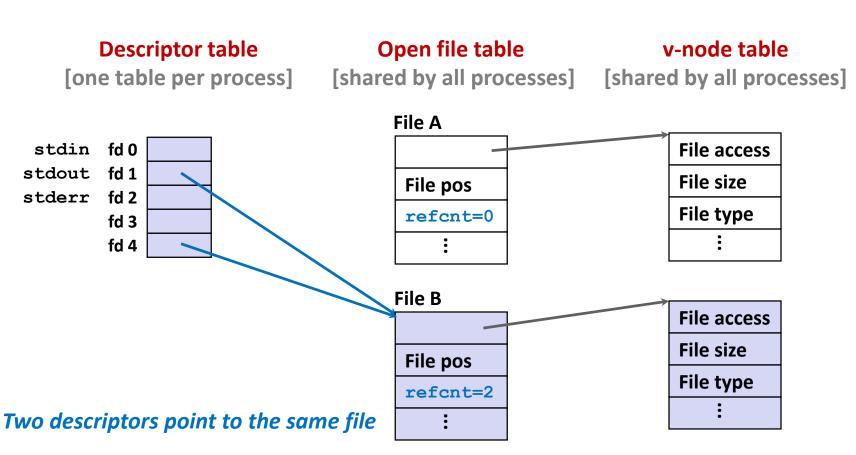

Happens in child executing shell code, before exec

I/O Redirection Example (cont.)

Step #2: call dup2 (4, 1)

cause fd=1 (stdout) to refer to disk file pointed at by fd=4

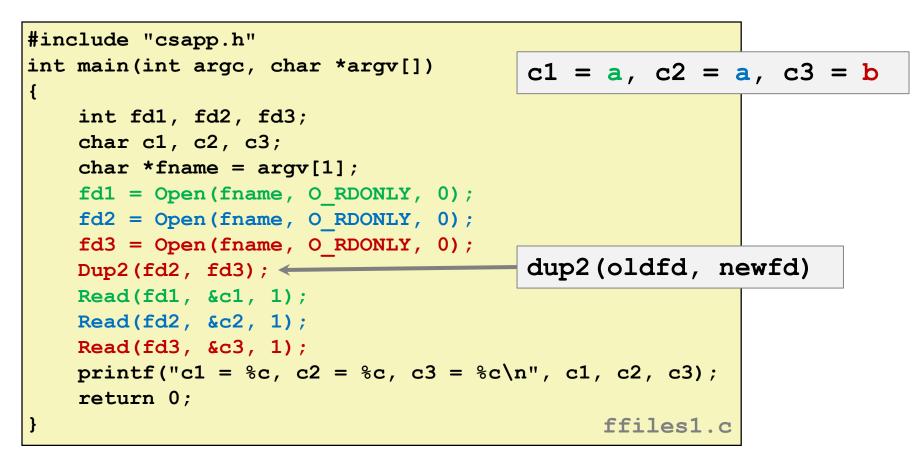

Warm-Up: I/O and Redirection Example

```
#include "csapp.h"
int main(int argc, char *argv[])
{
    int fd1, fd2, fd3;
    char c1, c2, c3;
    char *fname = argv[1];
    fd1 = Open(fname, O RDONLY, 0);
    fd2 = Open(fname, O RDONLY, 0);
    fd3 = Open(fname, O RDONLY, 0);
   Dup2(fd2, fd3);
   Read(fd1, &c1, 1);
   Read(fd2, &c2, 1);
   Read(fd3, &c3, 1);
   printf("c1 = %c, c2 = %c, c3 = %c\n", c1, c2, c3);
    return 0;
                                              ffiles1.c
```

What would this program print for file containing "abcde"?

Warm-Up: I/O and Redirection Example

What would this program print for file containing "abcde"?

Master Class: Process Control and I/O

```
#include "csapp.h"
int main(int argc, char *argv[])
{
    int fd1;
    int s = getpid() \& 0x1;
    char c1, c2;
    char *fname = argv[1];
    fd1 = Open(fname, O RDONLY, 0);
    Read(fd1, &c1, 1);
    if (fork()) { /* Parent */
        sleep(s);
        Read(fd1, &c2, 1);
        printf("Parent: c1 = %c, c2 = %c n", c1, c2);
    } else { /* Child */
        sleep(1-s);
        Read(fd1, &c2, 1);
        printf("Child: c1 = %c, c2 = %c n", c1, c2);
    }
    return 0;
                                             ffiles2.c
```

What would this program print for file containing "abcde"?

Master Class: Process Control and I/O

```
#include "csapp.h"
                                       Child: c1 = a, c2 = b
int main(int argc, char *argv[])
                                       Parent: c1 = a, c2 = c
Ł
   int fd1;
   int s = getpid() & 0x1;
   char c1, c2;
                                       Parent: c1 = a, c2 = b
   char *fname = argv[1];
                                       Child: c1 = a, c2 = c
   fd1 = Open(fname, O RDONLY, 0);
   Read(fd1, &c1, 1);
   if (fork()) { /* Parent */
                                       Bonus: Which way does it go?
       sleep(s);
       Read(fd1, &c2, 1);
       printf("Parent: c1 = %c, c2 = %c n", c1, c2);
    } else { /* Child */
       sleep(1-s);
       Read(fd1, &c2, 1);
       printf("Child: c1 = %c, c2 = %c n", c1, c2);
    }
   return 0;
                                           ffiles2.c
```

What would this program print for file containing "abcde"?

Today

- Unix I/O
- Metadata, sharing, and redirection
- RIO (robust I/O) package
- Standard I/O
- Closing remarks

The RIO Package (15-213/CS:APP Package)

RIO is a set of wrappers that provide efficient and robust I/O in apps, such as network programs that are subject to short counts

RIO provides two different kinds of functions

- Unbuffered input and output of binary data
 - rio_readn and rio_writen
- Buffered input of text lines and binary data
 - rio_readlineb and rio_readnb
 - Buffered RIO routines are thread-safe and can be interleaved arbitrarily on the same descriptor

Download from <u>http://csapp.cs.cmu.edu/3e/code.html</u>

→ src/csapp.c and include/csapp.h

Unbuffered RIO Input and Output

- Same interface as Unix read and write
- **Especially useful for transferring data on network sockets**

```
#include "csapp.h"
ssize_t rio_readn(int fd, void *usrbuf, size_t n);
ssize_t rio_writen(int fd, void *usrbuf, size_t n);
```

Return: num. bytes transferred if OK, 0 on EOF (rio_readn only), -1 on error

- rio readn returns short count only if it encounters EOF
 - Only use it when you know how many bytes to read
- rio_writen never returns a short count
- Calls to rio_readn and rio_writen can be interleaved arbitrarily on the same descriptor

Implementation of rio_readn

```
/*
* rio readn - Robustly read n bytes (unbuffered)
*/
ssize t rio readn(int fd, void *usrbuf, size t n)
{
   size t nleft = n;
   ssize t nread;
   char *bufp = usrbuf;
   while (nleft > 0) {
      if ((nread = read(fd, bufp, nleft)) < 0) {</pre>
          if (errno == EINTR) /* Interrupted by sig handler return */
             else
             return -1; /* errno set by read() */
      }
      else if (nread == 0)
                            /* EOF */
         break;
      nleft -= nread;
      bufp += nread;
   return (n - nleft); /* Return >= 0 */
                                                         csapr
```

Bryant and O manaron, computer systems. A programmer's perspective, minu cultion

Buffered RIO Input Functions

Efficiently read text lines and binary data from a file partially cached in an internal memory buffer

```
#include "csapp.h"
void rio_readinitb(rio_t *rp, int fd);
ssize_t rio_readlineb(rio_t *rp, void *usrbuf, size_t maxlen);
ssize_t rio_readnb(rio_t *rp, void *usrbuf, size_t n);
```

Return: num. bytes read if OK, 0 on EOF, -1 on error

- rio_readlineb reads a *text line* of up to maxlen bytes from file fd and stores the line in usrbuf
 - Especially useful for reading text lines from network sockets
- Stopping conditions
 - maxlen bytes read
 - EOF encountered
 - Newline ('\n') encountered

Buffered RIO Input Functions (cont)

```
#include "csapp.h"
```

```
void rio readinitb(rio t *rp, int fd);
```

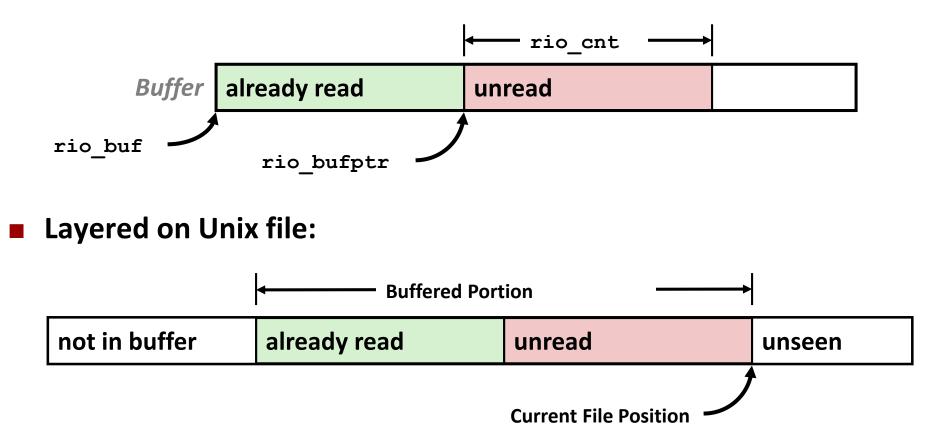

```
ssize_t rio_readlineb(rio_t *rp, void *usrbuf, size_t maxlen);
ssize t rio readnb(rio t *rp, void *usrbuf, size t n);
```

Return: num. bytes read if OK, 0 on EOF, -1 on error

- rio_readnb reads up to n bytes from file fd
- Stopping conditions
 - maxlen bytes read
 - EOF encountered
- Calls to rio_readlineb and rio_readnb can be interleaved arbitrarily on the same descriptor
 - Warning: Don't interleave with calls to rio_readn

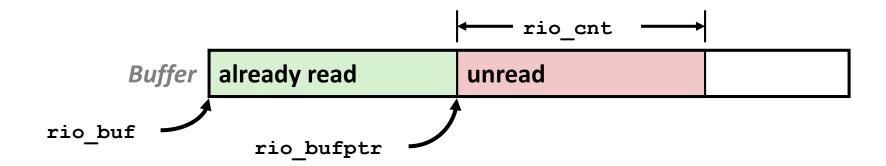

Buffered I/O: Implementation

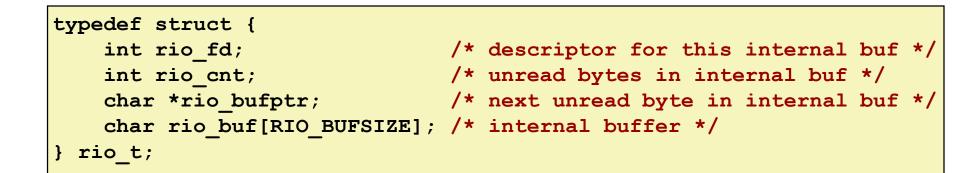

- For reading from file
- File has associated buffer to hold bytes that have been read from file but not yet read by user code

Buffered I/O: Declaration

All information contained in struct

RIO Example

 Copying the lines of a text file from standard input to standard output

```
#include "csapp.h"
int main(int argc, char **argv)
{
    int n;
    rio_t rio;
    char buf[MAXLINE];
    Rio_readinitb(&rio, STDIN_FILENO);
    while((n = Rio_readlineb(&rio, buf, MAXLINE)) != 0)
        Rio_writen(STDOUT_FILENO, buf, n);
    exit(0);
}
```

Today

- Unix I/O
- Metadata, sharing, and redirection
- RIO (robust I/O) package
- Standard I/O
- Closing remarks

Standard I/O Functions

- The C standard library (libc.so) contains a collection of higher-level standard I/O functions
 - Documented in Appendix B of K&R

Examples of standard I/O functions:

- Opening and closing files (fopen and fclose)
- Reading and writing bytes (fread and fwrite)
- Reading and writing text lines (fgets and fputs)
- Formatted reading and writing (fscanf and fprintf)

Standard I/O Streams

- Standard I/O models open files as streams
 - Abstraction for a file descriptor and a buffer in memory
- C programs begin life with three open streams (defined in stdio.h)
 - stdin (standard input)
 - stdout (standard output)
 - stderr (standard error)

```
#include <stdio.h>
extern FILE *stdin; /* standard input (descriptor 0) */
extern FILE *stdout; /* standard output (descriptor 1) */
extern FILE *stderr; /* standard error (descriptor 2) */
int main() {
   fprintf(stdout, "Hello, world\n");
}
```

Buffered I/O: Motivation

- Applications often read/write one character at a time
 - getc, putc, ungetc
 - gets, fgets
 - Read line of text one character at a time, stopping at newline
- Implementing as Unix I/O calls expensive
 - read and write require Unix kernel calls
 - > 10,000 clock cycles

Solution: Buffered read

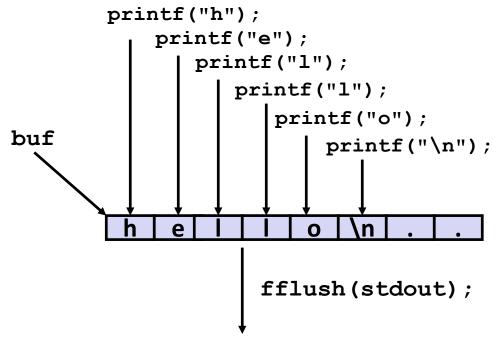

- Use Unix read to grab block of bytes
- User input functions take one byte at a time from buffer
 - Refill buffer when empty

Buffer already read

unread

Buffering in Standard I/O

Standard I/O functions use buffered I/O

write(1, buf, 6);

Buffer flushed to output fd on "\n", call to fflush or exit, or return from main.

Bryant and O'Hallaron, Computer Systems: A Programmer's Perspective, Third Edition

Standard I/O Buffering in Action

You can see this buffering in action for yourself, using the always fascinating Linux strace program:

```
#include <stdio.h>
int main()
{
    printf("h");
    printf("e");
    printf("l");
    printf("l");
    printf("l");
    printf("\n");
    fflush(stdout);
    exit(0);
}
```

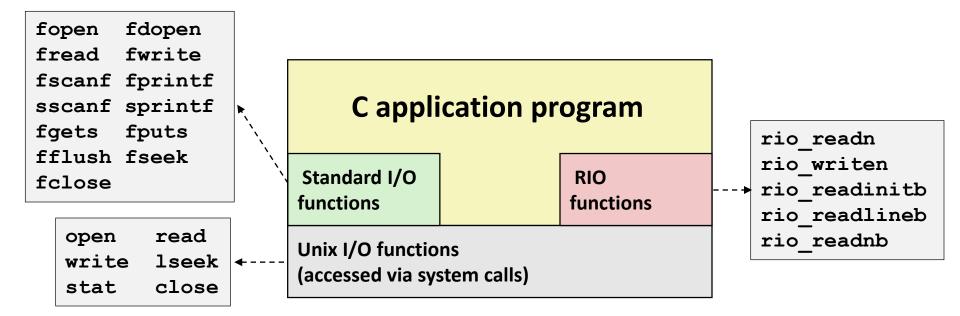

```
linux> strace ./hello
execve("./hello", ["hello"], [/* ... */]).
...
write(1, "hello\n", 6) = 6
...
exit_group(0) = ?
```

- Standard I/O
- Closing remarks

Unix I/O vs. Standard I/O vs. RIO

Standard I/O and RIO are implemented using low-level Unix I/O

Which ones should you use in your programs?

Pros and Cons of Unix I/O

Pros

- Unix I/O is the most general and lowest overhead form of I/O
 - All other I/O packages are implemented using Unix I/O functions
- Unix I/O provides functions for accessing file metadata
- Unix I/O functions are async-signal-safe and can be used safely in signal handlers

Cons

- Dealing with short counts is tricky and error prone
- Efficient reading of text lines requires some form of buffering, also tricky and error prone
- Both of these issues are addressed by the standard I/O and RIO packages

Pros and Cons of Standard I/O

Pros:

- Buffering increases efficiency by decreasing the number of read and write system calls
- Short counts are handled automatically

Cons:

- Provides no function for accessing file metadata
- Standard I/O functions are not async-signal-safe, and not appropriate for signal handlers
- Standard I/O is not appropriate for input and output on network sockets
 - There are poorly documented restrictions on streams that interact badly with restrictions on sockets (CS:APP3e, Sec 10.11)

Choosing I/O Functions

General rule: use the highest-level I/O functions you can

- Many C programmers are able to do all of their work using the standard I/O functions
- But, be sure to understand the functions you use!

When to use standard I/O

When working with disk or terminal files

When to use raw Unix I/O

- Inside signal handlers, because Unix I/O is async-signal-safe
- In rare cases when you need absolute highest performance

When to use RIO

- When you are reading and writing network sockets
- Avoid using standard I/O on sockets

Aside: Working with Binary Files

Functions you should never use on binary files

- Text-oriented I/O: such as fgets, scanf, rio_readlineb
 - Interpret EOL characters.
 - Use functions like rio_readn or rio_readnb instead
- String functions
 - strlen, strcpy, strcat
 - Interprets byte value 0 (end of string) as special

I/O Questions in Exams

Problem 10. (6 points):

Unix I/O.

A. Suppose that the disk file foobar.txt consists of the six ASCII characters "foobar". What is the output of the following program?

```
/* any necessary includes */
char buf [20] = \{0\}; /* init to all zeroes */
int main(int argc, char* argv[]) {
   int fd1 = open("foobar.txt", O RDONLY);
   int fd2 = open("foobar.txt", O RDONLY);
   dup2(fd2, fd1);
   read(fd1, buf, 3);
   close(fd1);
                                     ****
   read(fd2, &buf[3], 3);
                                     Problem 10
   close(fd2);
                                     ****
   printf("buf = %s\n", buf);
   return 0;
                                     A. Output: buf = foobar
}
Output: buf = ____
```

Fun with File Descriptors (1)

```
#include "csapp.h"
int main(int argc, char *argv[])
{
    int fd1, fd2, fd3;
    char c1, c2, c3;
    char *fname = argv[1];
    fd1 = Open(fname, O RDONLY, 0);
    fd2 = Open(fname, O RDONLY, 0);
    fd3 = Open(fname, O RDONLY, 0);
   Dup2(fd2, fd3);
   Read(fd1, &c1, 1);
   Read(fd2, &c2, 1);
   Read(fd3, &c3, 1);
   printf("c1 = %c, c2 = %c, c3 = %c\n", c1, c2, c3);
    return 0;
                                              ffiles1.c
```

What would this program print for file containing "abcde"?

Fun with File Descriptors (2)

```
#include "csapp.h"
int main(int argc, char *argv[])
{
    int fd1;
    int s = getpid() \& 0x1;
    char c1, c2;
    char *fname = argv[1];
    fd1 = Open(fname, O RDONLY, 0);
    Read(fd1, &c1, 1);
    if (fork()) { /* Parent */
        sleep(s);
        Read(fd1, &c2, 1);
        printf("Parent: c1 = c, c2 = c, c1, c2);
    } else { /* Child */
        sleep(1-s);
        Read(fd1, &c2, 1);
       printf("Child: c1 = %c, c2 = %c n", c1, c2);
    }
    return 0;
                                            ffiles2.c
```

What would this program print for file containing "abcde"?

Bryant and O'Hallaron, Computer Systems: A Programmer's Perspective, Third Edition

Fun with File Descriptors (3)

```
#include "csapp.h"
int main(int argc, char *argv[])
{
    int fd1, fd2, fd3;
    char *fname = argv[1];
    fd1 = Open(fname, O CREAT|O TRUNC|O RDWR, S IRUSR|S IWUSR);
   Write(fd1, "pqrs", 4);
    fd3 = Open(fname, O APPEND|O WRONLY, 0);
   Write(fd3, "jklmn", 5);
    fd2 = dup(fd1); /* Allocates descriptor */
   Write(fd2, "wxyz", 4);
   Write(fd3, "ef", 2);
    return 0;
                                                       ffiles3.c
```

What would be the contents of the resulting file?

Accessing Directories

Only recommended operation on a directory: read its entries

- dirent structure contains information about a directory entry
- DIR structure contains information about directory while stepping through its entries

```
#include <sys/types.h>
#include <dirent.h>
Ł
 DIR *directory;
  struct dirent *de;
  if (!(directory = opendir(dir name)))
      error("Failed to open directory");
  while (0 != (de = readdir(directory))) {
      printf("Found file: %s\n", de->d name);
  }
  closedir(directory);
```
