Problem 4. (14 points):

Process control.

Consider the following C program:

```c
int main()
{
    pid_t pid;
    int status, counter = 4;

    while(counter > 0)
    {
        pid = fork();

        if(pid)
        {
            counter /= 2;
        }
        else
        {
            printf("%d", counter); /* (1) */
            break;
        }
    }

    if(pid)
    {
        waitpid(-1, &status, 0);
        counter += WEXITSTATUS(status);

        waitpid(-1, &status, 0);
        counter += WEXITSTATUS(status);

        printf(";%d", counter); /* (2) */
    }

    return counter;
}
```
Use the following assumptions to answer the questions:

- All processes run to completion, and no system calls fail.
- \texttt{printf} is atomic and calls \texttt{fflush(stdout)} after printing its argument(s) but before returning.

For each question, there may be more blanks than necessary.

A. List every individual digit that can be emitted by a call to \texttt{printf}. Include any digits that can be printed along with the semicolon by the \texttt{printf} annotated with (2). For example, if 1521;3 were a possible output of the program, the solutions would include 1, 2, 3, and 5.

\[
\begin{array}{cccc}
\quad & \quad & \quad & \\
\quad & \quad & \quad & \\
\quad & \quad & \quad & \\
\quad & \quad & \quad & \\
\end{array}
\]

B. Notice that the \texttt{printf} annotated with (2) emits a semicolon in addition to a digit. List all of the digit sequences that can be printed \textit{before} the semicolon is emitted. For example, if 1521;3 were a possible output of the program, 1521 would be one solution.

\[
\begin{array}{cccc}
\quad & \quad & \quad & \\
\quad & \quad & \quad & \\
\quad & \quad & \quad & \\
\quad & \quad & \quad & \\
\end{array}
\]

C. Now list all of the digit sequences that can be printed \textit{after} the semicolon is emitted.

\[
\begin{array}{cccc}
\quad & \quad & \quad & \\
\quad & \quad & \quad & \\
\quad & \quad & \quad & \\
\quad & \quad & \quad & \\
\end{array}
\]
Problem 3. (15 points):

Suppose we have the following two .c files:

alarm.c

```c
int counter;

void sigalrm_handler (int num) {
    counter += 1;
}

int main (void) {
    signal(SIGALRM, &sigalrm_handler);
    counter = 2;
    alarm(1);
    sleep(1);
    counter -= 3;
    exit(counter);
    return 0;
}
```

test.c

```c
int counter;

void sigchld_handler(int num) {
    int i;
    wait(&i);
    counter += WEXITSTATUS(i);
}

int main (void) {
    signal(SIGCHLD, &sigchld_handler);
    counter = 3;
    if (!fork()) {
        counter++;
        execl("alarm", "alarm", NULL);
    }
    sleep(2);
    counter *= 3;
    printf("%d\n", counter);
    exit(0);
}
```

Assume that all system calls succeed and that all C arithmetic statements are atomic.

The files are compiled as follows:

```
gcc -o alarm alarm.c
```

```
gcc -o fork fork.c
```

Suppose we run ./fork at the terminal. What are the possible outputs to the terminal?
We consider a 128 byte data cache that is 2-way associative and can hold 4 doubles in every cache line. A double is assumed to require 8 bytes.

For the below code we assume a cold cache. Further, we consider an array $A$ of 32 doubles that is cache-aligned (that is, $A[0]$ is loaded into the first slot of a cache line in the first set). All other variables are held in registers. The code is parameterized by positive integers $m$ and $n$ that satisfy $m \times n = 32$ (i.e., if you know one you know the other).

Recall that miss rate is defined as $\frac{\text{#misses}}{\text{#accesses}}$.

```c
float A[32], t = 0;
for(int i = 0; i < m; i++)
    for(int j = 0; j < n; j++)
        t += A[j*m + i];
```

Answer the following:

1. How many doubles can the cache hold?
2. How many sets does the cache have?
3. For $m = 1$:
   (a) Determine the miss rate.
   (b) What kind of misses occur?
   (c) Does the code have temporal locality with respect to accesses of $A$ and this cache?
4. For \( m = 2 \):
   
   (a) Determine the miss rate.

   (b) What kind of misses occur?

5. For \( m = 16 \):
   
   (a) Determine the miss rate.

   (b) What kind of misses occur?

   (c) Does the code have spatial locality with respect to accesses of \( A \) and this cache?
Review Problem 4

Problem 4. (9 points):

Consider the C code below:

```c
int fdplay() {
    int pid;
    int fd1, fd2;

    fd1 = open("/file1", O_RDWR);
    dup2(fd1, 1);
    printf("A");
    if ((pid = fork()) == 0) {
        printf("B");
        fd2 = open("/file1", O_RDWR);
        dup2(fd2, 1);
        printf("C");
        /* POINT X */
    } else {
        waitpid(pid, NULL, 0);
        printf("D");
        close(fd1);
        printf("E");
    }
    exit(2);
}
```

A. How many processes share the open file structure referred to by \texttt{fd1} at "POINT X" in the code?

B. How many file descriptors (total among all processes) share the open file structure referred to by \texttt{fd1} at "POINT X" in the code?

C. Assuming that \texttt{/file1} was empty before running this code, what are its contents after the execution is complete?
Problem 9. (16 points):
This problem tests your understanding of exceptional control flow in C programs. Assume we are running code on a Unix machine. The following problems all concern the value of the variable `counter`.

Part I (6 points)

```c
int counter = 0;

int main()
{
    int i;

    for (i = 0; i < 2; i ++){
        fork();
        counter ++;
        printf("counter = %d\n", counter);
    }

    printf("counter = %d\n", counter);
    return 0;
}
```

A. How many times would the value of `counter` be printed: ______________

B. What is the value of `counter` printed in the first line? ______________

C. What is the value of `counter` printed in the last line? ______________
**Part II (6 points)**

```c
pid_t pid;
int counter = 0;

void handler1(int sig)
{
    counter ++;
    printf("counter = %d\n", counter);
    fflush(stdout); /* Flushes the printed string to stdout */
    kill(pid, SIGUSR1);
}

void handler2(int sig)
{
    counter += 3;
    printf("counter = %d\n", counter);
    exit(0);
}

main()
{
    signal(SIGUSR1, handler1);
    if ((pid = fork()) == 0) {
        signal(SIGUSR1, handler2);
        kill(getppid(), SIGUSR1);
        while(1) {};
    }
    else {
        pid_t p; int status;
        if ((p = wait(&status)) > 0) {
            counter += 2;
            printf("counter = %d\n", counter);
        }
    }
}
```

What is the output of this program?
Part III (4 points)

int counter = 0;

void handler(int sig)
{
    counter ++;
}

int main()
{
    int i;

    signal(SIGCHLD, handler);

    for (i = 0; i < 5; i ++){
        if (fork() == 0){
            exit(0);
        }
    }

    /* wait for all children to die */
    while (wait(NULL) != -1);

    printf("counter = %d\n", counter);
    return 0;
}

A. Does the program output the same value of counter every time we run it?  Yes  No

B. If the answer to A is Yes, indicate the value of the counter variable. Otherwise, list all possible values of the counter variable.

Answer: counter = ____________________
Problem 11. (9 points):

Synchronization. This problem is about using semaphores to synchronize access to a shared bounded FIFO queue in a producer/consumer system with an arbitrary number of producers and consumers.

- The queue is initially empty and has a capacity of 10 data items.
- Producer threads call the insert function to insert an item onto the rear of the queue.
- Consumer threads call the remove function to remove an item from the front of the queue.
- The system uses three semaphores: mutex, items, and slots.

Your task is to use P and V semaphore operations to correctly synchronize access to the queue.

A. What is the initial value of each semaphore?

mutex = _______
items = _______
slots = _______

B. Add the appropriate P and V operations to the pseudo-code for the insert and remove functions:

```c
void insert(int item)
{
    /* Insert sem ops here */
    add_item(item);
    /* Insert sem ops here */
}

int remove()
{
    /* Insert sem ops here */
    item = remove_item();
    /* Insert sem ops here */
    return item;
}
```
Assembly/C translation.

Consider the following C code and assembly code for a curiously-named function:

```c
typedef struct node
{
    void *data;
    struct node *next;
} node_t;

node_t *lmao(node_t *n, int f(node_t *))
{
    node_t *a, *b;
    
    if(________________)
    {
        return NULL;
    }
    
    a = ______________;
    
    if(________________)
    {
        b = ______________;
        b->data = n->data;
        b->next = ______________;
        return b;
    }
    
    return ______________;
}
```

Using your knowledge of C and assembly, fill in the blanks in the C code for `lmao` with the appropriate expressions. (Note: 0x400498 is the address of the C standard library function `malloc`.)
Review Problem 8

Problem 6. (0xa points):

The stack discipline. This problem deals with stack frames in Intel IA-32 machines. Consider the following C function and corresponding assembly code.

```c
struct node_t;
typedef struct node_t{
    void * elem;
    struct node_t *left;
    struct node_t *right;
} node;

void oak(node * tree, void (*printFunc)(node *)){
    /*POINT A*/
    (*printFunc)(tree);
    if (tree->left) {
        /*POINT B*/
        oak(tree->left,printFunc);
    }
    if (tree->right) {
        oak(tree->right,printFunc);
    }
}
```

```assembly
00000000 <oak>:
0: 55 push %ebp
1: 89 e5 mov %esp,%ebp
3: 83 ec 18 sub $0x18,%esp
6: 89 5d f8 mov %ebx,0xfffffff8(%ebp)
9: 89 75 fc mov %esi,0xffffffff(%ebp)
c: 8b 5d 08 mov 0x8(%ebp),%ebx
f: 8b 75 0c mov 0xc(%ebp),%esi
12: 89 1c 24 mov %ebx,(%esp)
15: ff d6 call *%esi
17: 8b 43 04 mov 0x4(%ebx),%eax
1a: 85 c0 test %eax,%eax
1c: 74 0c je 2a <oak+0x2a>
1e: 89 74 24 04 mov %esi,0x4(%esp)
22: 89 04 24 mov %eax,(%esp)
25: e8 fc ff ff ff call 26 <oak+0x26>
2a: 8b 43 08 mov 0x8(%ebx),%eax
2d: 85 c0 test %eax,%eax
2f: 74 0c je 3d <oak+0x3d>
31: 89 74 24 04 mov %esi,0x4(%esp)
35: 89 04 24 mov %eax,(%esp)
38: e8 fc ff ff ff call 39 <oak+0x39>
3d: 8b 5d f8 mov 0xffffffff(%ebp),%ebx
40: 8b 75 fc mov 0xffffffff(%ebp),%esi
43: 89 ec mov %ebp,%esp
45: 5d pop %ebp
46: c3 ret
```

(over)
Please draw a picture of the stack frame, starting with any arguments that might be placed on the stack for the `oak` function, showing the stack at each of points A, and B, as specified in the code above. Your diagram should only include actual values where they are known, if you do not know the value that will be placed on the stack, simply label what it is (i.e., "old ebp").
Problem 9. (12 points):

Address translation. This problem concerns the way virtual addresses are translated into physical addresses. Imagine a system has the following parameters:

- Virtual addresses are 20 bits wide.
- Physical addresses are 18 bits wide.
- The page size is 1024 bytes.
- The TLB is 2-way set associative with 16 total entries.

The contents of the TLB and the first 32 entries of the page table are shown as follows. All numbers are given in hexadecimal.

<table>

Page 15 of 20
Part 1

1. The diagram below shows the format of a virtual address. Please indicate the following fields by labeling the diagram:

   - **VPO**: The virtual page offset
   - **VPN**: The virtual page number
   - **TLBI**: The TLB index
   - **TLBT**: The TLB tag

   19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

2. The diagram below shows the format of a physical address. Please indicate the following fields by labeling the diagram:

   - **PPO**: The physical page offset
   - **PPN**: The physical page number

   17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
Part 2

For the given virtual addresses, please indicate the TLB entry accessed and the physical address. Indicate whether the TLB misses and whether a page fault occurs. If there is a page fault, enter “-” for “PPN” and leave the physical address blank.

**Virtual address: 078E6**
