

# Classical Loop Optimizations

15-745 Optimizing Compilers  
Spring 2006

Peter Lee

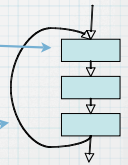

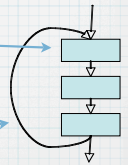

## Reminders

- \* Task 1 is due
- \* Task 2 available shortly
- \* Read 13.2 (loop-invariant code motion) and Ch.14 (induction variables)

## Common loop optimizations

- \* **Hoisting of loop-invariant computations**
  - \* pre-compute before entering the loop
- \* **Elimination of induction variables**
  - \* change  $p=i*w+b$  to  $p=b+w$ , when  $w,b$  invariant
- \* **Elimination of null and array-bounds checks**
  - \* use laws of arithmetic to prove integer range
- \* **Loop unrolling**
  - \* to reduce number of control transfers
- \* **Loop permutation**
  - \* to improve cache memory performance

## Finding loops

- \* To optimize loops, we need to find them!
- \* Specifically:
  - \* loop-header node(s) 
  - \* nodes in a loop that have immediate predecessors not in the loop
  - \* back edge(s) 
  - \* control-flow edges to previously executed nodes
- \* all nodes in the loop body

## Finding loops in L3

- \* L3 has only well-structured control-flow constructs
- \* Finding L3 loops is easy
- \* the translator can mark every header node when creating the IR

In a **loop-nest tree**, each node represents the blocks of a loop, and parent nodes are enclosing loops

The leaves of the tree are the inner-most loops

## Control-flow analysis

- \* Many languages have goto and other complex control, so loops can be hard to find in general
- \* Determining the control structure of a program is called **control-flow analysis**
- \* Based on the notion of **dominators**

## Dominators

- \* a dom b
- \* node a **dominates** b if every possible execution path from entry to b includes a
- \* a sdom b
- \* a **strictly dominates** b if a dom b and  $a \neq b$
- \* a idom b
- \* a **immediately dominates** b if there is no c such that a sdom c and c sdom b

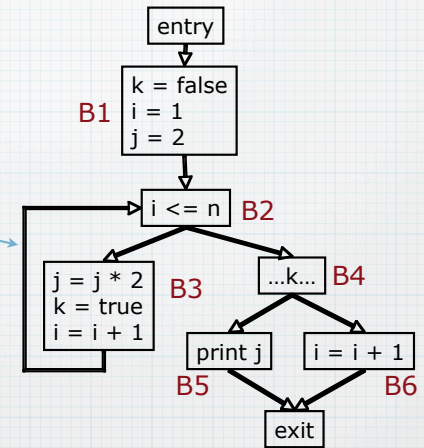

## Some properties

- \*  $\text{idom}(n)$  is unique
- \* The  $\text{dom}$  relation is a partial ordering
  - \* reflexive, antisymmetric, and transitive

## Back edges and loop headers

A control-flow edge from node  $B3$  to  $B2$  is a **back edge** if  $B2 \text{ dom } B3$

Furthermore, in that case node  $B2$  is a **loop header**

## Natural loop

- \* Consider a back edge from node  $n$  to node  $h$
- \* The **natural loop** of  $n \rightarrow h$  is the set of nodes  $L$  such that for all  $x \in L$ :
  - \*  $h \text{ dom } x$  and
  - \* there is a path from  $x$  to  $n$  not containing  $h$

A simple example...

nested loops

What about this case?

loop with "continue"

What about this case?

conditional in loop

More later...

- \* We'll have more to say about dominators, including how to compute them efficiently, next week

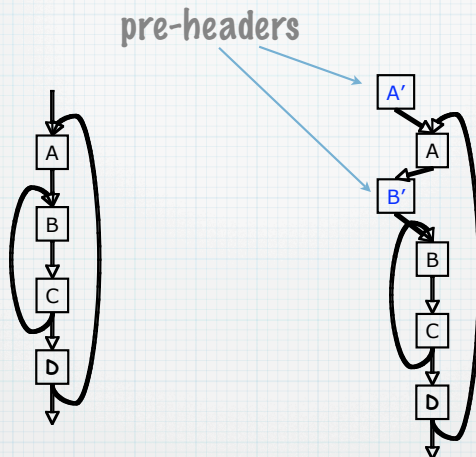

Loop optimizations:  
Hoisting of loop-invariant  
computations

## Loop-invariant computations

- \* A definition
  - \*  $t = x \oplus y$
- \* in a loop is (conservatively) **loop-invariant** if
  - \*  $x$  and  $y$  are constants, or
  - \* all reaching definitions of  $x$  and  $y$  are outside the loop, or
  - \* only one definition reaches  $x$  (or  $y$ ), and that definition is loop-invariant

## Hoisting

- \* In order to “hoist” a loop-invariant computation out of a loop, we need a place to put it
- \* We could copy it to all immediate predecessors (except along the back-edge) of the loop header...
- \* ...But we can avoid code duplication by inserting a new block, called the **pre-header**

## Hoisting conditions

- \* For a loop-invariant definition
  - \*  $d: t = x \oplus y$
- \* we can hoist  $d$  into the loop's pre-header if
  1.  $d$ 's block dominates all loop exits at which  $t$  is live-out, and
  2. there is only one definition of  $t$  in the loop, and
  3.  $t$  is not live-out of the pre-header

## We need to be careful...

- \* All hoisting conditions must be satisfied!

```
L0:
  t = 0
L1:
  i = i + 1
  t = a * b
  M[i] = t
  if i < N goto L1
L2:
  x = t
```

OK

```
L0:
  t = 0
L1:
  if i >= N goto L2
  i = i + 1
  t = a * b
  M[i] = t
  goto L1
L2:
  x = t
```

violates 1,3

```
L0:
  t = 0
L1:
  i = i + 1
  t = a * b
  M[i] = t
  t = 0
  M[j] = t
  if i < N goto L1
L2:
```

violates 2

## Loop optimizations: Induction-variable elimination

## The basic idea of IVE

- \* Suppose we have a loop variable
  - \*  $i$  initially 0; each iteration  $i = i + 1$
- \* and a variable that linearly depends on it
  - \*  $x = i * c_1 + c_2$
- \* In such cases, we can try to
  - \* initialize  $x = i_0 * c_1 + c_2$
  - \* increment  $x$  by  $c_1$  each iteration

## Is it faster?

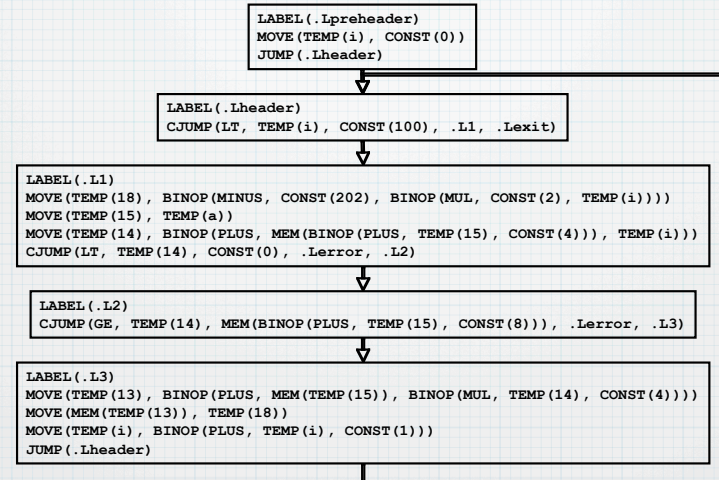

- \* On some hardware, adds are much faster than multiplies
- \* Furthermore, one fewer value is computed, thus potentially saving a register
  - \* and decreasing the possibility of spilling

## An example

```
void p() {
  var a : int*;
  var i : int;

  a = alloc(100,int);
  for (i=0; i<100; i=i+1)
    a[i] = 202 - 2 * i;
}
```

## IR for the loop

## Loop preparation

- \* Before attempting IVE, it is best to perform first:
  - \* constant propagation & constant folding
  - \* copy propagation
  - \* loop-invariant hoisting

## Copy propagation

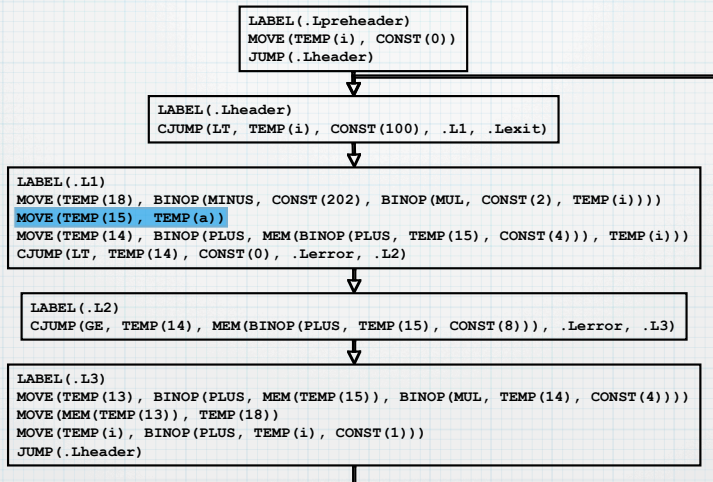

```
y = x;
...
z = y + 1;      →      y = x;
                  ...
                  z = x + 1;
```

If there have been no changes to  $x$  after a copy into  $y$ , we can just use  $x$  instead of  $y$

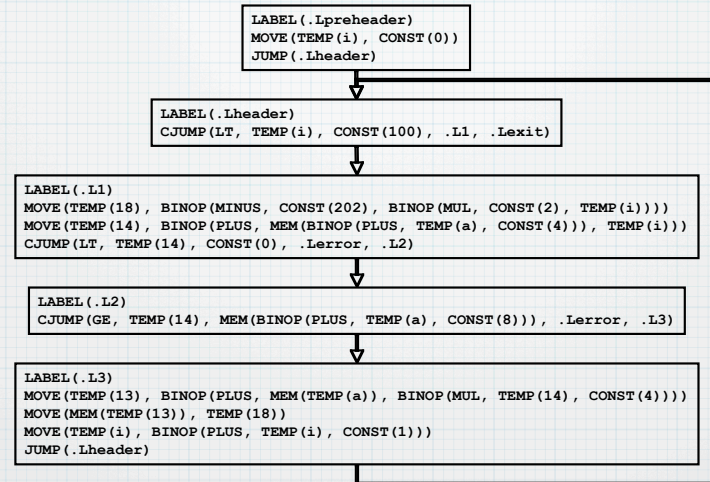

Dataflow analysis:

- forward analysis
- gen values: copy stmts of the form,  $d:y=x$
- kill: if  $x$  is defined, then kill all  $d$  with  $x$  on rhs

## IR for the loop

## After copy propagation

## Fat pointer representation

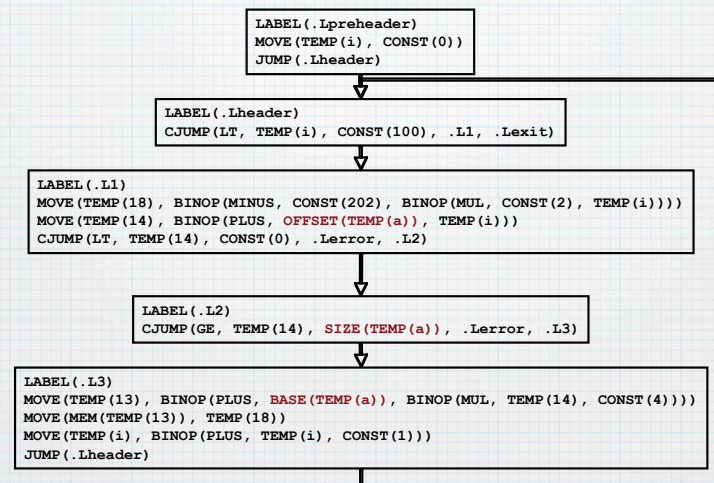

In typical implementations, the fields of a fat pointer are **immutable**

This means the base, offset, and size values for a can be considered loop-invariant

Sometimes convenient to reflect this in the IR...

## With immutable fields

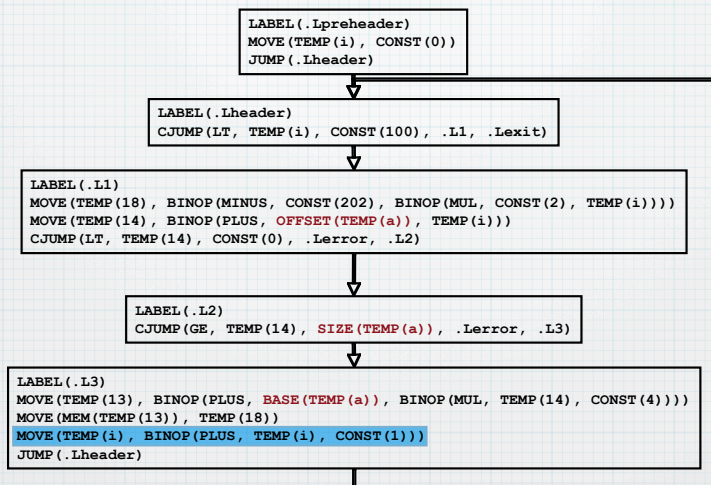

# Induction variables

- \* Observe: Some variables change by a constant amount on each iteration
- \*  $TEMP(i)$ : init 0; increments by 1
- \*  $TEMP(18)$ : init 202; decrements by 2
- \*  $TEMP(14)$ : init  $offset(a)$ ; increments by 1
- \*  $TEMP(13)$ : init  $\&a[offset(a)]$ ; inc by 4
- \* These are all **induction variables**

# Basic induction variables

- \*  $TEMP(i)$  is a **basic induction variable**
- \* aka **independent induction variable**
- \* The only modifications to  $TEMP(i)$  are of the form:
  - \*  $TEMP(i) = TEMP(i) + c$
  - \* where  $c$  is loop-invariant

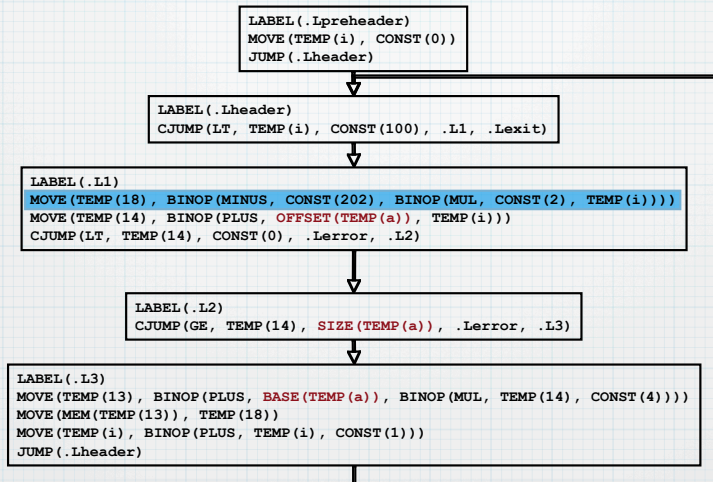

# Basic induction variable

# Derived induction variables

- \*  $TEMP(18)$  has the form
  - \*  $TEMP(18) = i * c_1 + c_2$
  - \* where
    - \*  $c_1, c_2$  are loop-invariant, and
    - \*  $i$  is an induction variable
- \*  $TEMP(18)$  is a **derived induction variable**
- \* aka **dependent induction variable**

## Derived induction variable

## The basic idea of IVE

- \* We have a basic IV
- \*  $TEMP(i) = TEMP(i) + 1$
- \* and derived IV
- \*  $TEMP(18) = TEMP(i) * -2 + 202$
- \* So, we can
- \* initialize  $TEMP(18) = TEMP(i)_i * -2 + 202$
- \* increment  $TEMP(18)$  by  $1 * -2$  each iteration

## How to do it, step 1

- \* First, find the basic IVs
- \* scan loop body for defs of the form
  - \*  $x = x + c$ , where  $c$  is loop-invariant
- \* record these basic IVs as
  - \*  $x = (x, 1, c)$
  - \* this represents the IV:  $x = x * 1 + c$

## How to do it, step 2

- \* Scan for derived IVs of the form
  - \*  $k = i * c_1 + c_2$
  - \* where  $i$  is a basic IV and this is the only def of  $k$  in the loop
- \* We say  $k$  is in the family of  $i$
- \* Record as  $k = (i, c_1, c_2)$

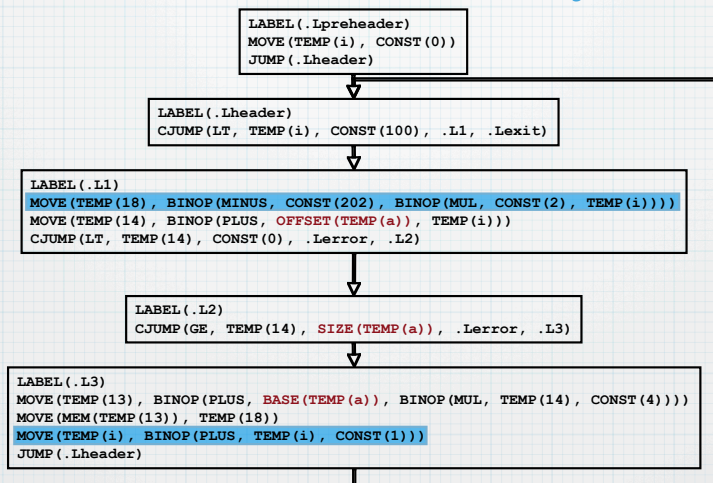

## How to do it, step 3

- \* Iterate, looking for derived IVs of the form
  - \*  $k = j * c_1 + c_2$
  - \* where IV  $j = (i, a, b)$ , and
  - \* this is the only def of  $k$  in the loop, and
  - \* there is no def of  $i$  between the def of  $j$  and the def of  $k$
- \* Record as  $k = (i, a * c_1, b * c_1 + c_2)$

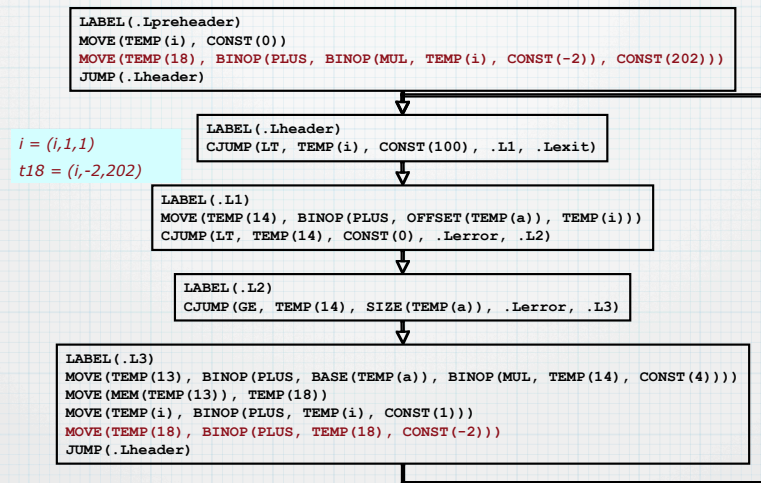

## How to do it, step 4

- \* For an induction variable  $k = (i, c_1, c_2)$ 
  - \* initialize  $k = i * c_1 + c_2$  in the preheader
  - \* replace  $k$ 's def in the loop by
    - \*  $k = k + c_1$
  - \* make sure to do this after  $i$ 's def

## Back to our example

## First round of IVE

# More IVE

$i = (i, 1, 1)$   
 $t18 = (i, -2, 202)$   
 $t14 = (i, 1, \text{offset}(a))$   
 $t13 = (i, 4, \text{offset}(a)*4 + \text{base}(a))$

```

```

LABEL (.L3)
MOVE (MEM (TEMP(13)), TEMP(18))
MOVE (TEMP(i), BINOP (PLUS, TEMP(i), CONST(1)))
MOVE (TEMP(18), BINOP (PLUS, TEMP(18), CONST(-2)))
MOVE (TEMP(14), BINOP (PLUS, TEMP(14), CONST(1)))
MOVE (TEMP(13), BINOP (PLUS, TEMP(13), CONST(4)))
JUMP (.Lheader)

```

# The simple case

- \* If index expression  $i$  is loop invariant, then we can hoist the bounds check into the preheader

# Case: basic IV

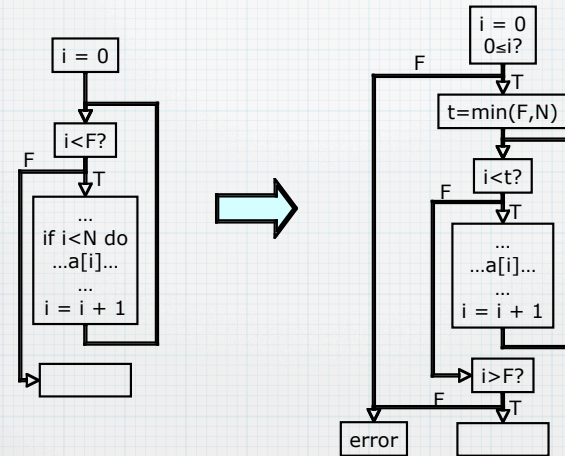

- \* If  $i$  is a basic IV,  $(i, 1, c)$ , and  $i$  is used in a loop-test of the form
  - \*  $\text{CJUMP}(\text{LT}, i, F, L1, L2)$ , or
  - \*  $\text{CJUMP}(\text{GE}, i, F, L2, L1)$ , or
  - \*  $\text{CJUMP}(\text{GT}, F, i, L1, L2)$ , or
  - \*  $\text{CJUMP}(\text{LE}, F, i, L2, L1)$ 
    - \* where  $L2$  is out of the loop
- \* Then we can...

loop-test bounds  $i$

## Basic IV case

- \* Then we can
  - \* insert a check for  $0 \leq i$  in the preheader
  - \* compute  $t = \min(F, \text{size}(a))$ 
    - \* either statically or in preheader
  - \* replace  $F$  with  $t$  in the loop test
  - \* add a check for  $i \geq F$  at the loop exits

## Typical situation

## Our example

```

LABEL (.Lpreheader)
MOVE (TEMP (i), CONST (0))
MOVE (TEMP (18), BINOP (PLUS, BINOP (MUL, TEMP (i), CONST (-2)), CONST (202)))
MOVE (TEMP (14), BINOP (PLUS, OFFSET (TEMP (a)), TEMP (i)))
MOVE (TEMP (13), BINOP (PLUS, BASE (TEMP (a)), BINOP (MUL, TEMP (14), CONST (4))))
JUMP (.Lheader)
    
```

```

LABEL (.Lheader)
CJUMP (LT, TEMP (i), CONST (100), .L1, .Lexit)
    
```

```

LABEL (.L1)
CJUMP (BELOW, TEMP (14), SIZE (TEMP (a)), .Lerror, .L3)
    
```

```

LABEL (.L3)
MOVE (MEM (TEMP (13)), TEMP (18))
MOVE (TEMP (i), BINOP (PLUS, TEMP (i), CONST (1)))
MOVE (TEMP (18), BINOP (PLUS, TEMP (18), CONST (-2)))
MOVE (TEMP (14), BINOP (PLUS, TEMP (14), CONST (1)))
MOVE (TEMP (13), BINOP (PLUS, TEMP (13), CONST (4)))
JUMP (.Lheader)
    
```

## Case: derived IV

- \* If  $j$  is derived IV,  $(i, c_1, c_2)$ , for  $i$  in the loop test
  - \* since  $j = i * c_1 + c_2$ , we can verify
    - \*  $-c_2/c_1 \leq i < (\text{size}(a) - c_2)/c_1$
- \* So:
  - \* insert check for  $-c_2/c_1 \leq i$  in preheader
  - \* compute  $t = \min(F, (\text{size}(a) - c_2)/c_1)$  in preheader
  - \* replace  $F$  with  $t$  in loop test
  - \* add a check for  $i > F$  in loop exits

## Our example

$i = (i, 1, 1)$   
 $t14 = (i, 1, \text{offset}(a))$

```
LABEL(.Lpreheader)
MOVE(TEMP(i), CONST(0))
MOVE(TEMP(18), BINOP(PLUS, BINOP(MUL, TEMP(i), CONST(-2)), CONST(202)))
MOVE(TEMP(14), BINOP(PLUS, OFFSET(TEMP(a)), TEMP(i)))
MOVE(TEMP(13), BINOP(PLUS, BASE(TEMP(a)), BINOP(MUL, TEMP(14), CONST(4))))
CJUMP(LE, UNOP(NEG(OFFSET(TEMP(a)))), TEMP(i), .Lpre, .Lerror)
```

```
LABEL(.Lpre)
MOVE(TEMP(20), BINOP(MINUS, SIZE(TEMP(a)), OFFSET(TEMP(a))))
MOVE(TEMP(21), BINOP(MIN, CONST(100), TEMP(20)))
CJUMP(LT, TEMP(i), CONST(100), .Lheader, .Lexit)
```

```
LABEL(.Lheader)
CJUMP(LT, TEMP(i), TEMP(21), .L3, .Lexit)
```

```
LABEL(.L3)
MOVE(MEM(TEMP(13)), TEMP(18))
MOVE(TEMP(i), BINOP(PLUS, TEMP(i), CONST(1)))
MOVE(TEMP(18), BINOP(PLUS, TEMP(18), CONST(-2)))
MOVE(TEMP(14), BINOP(PLUS, TEMP(14), CONST(1)))
MOVE(TEMP(13), BINOP(PLUS, TEMP(13), CONST(4)))
JUMP(.Lheader)
```

```
LABEL(.Lexit)
CJUMP(GE, TEMP(i), CONST(100), .Lnext, .Lerror)
```

## Other Approaches

## Bounds checks are expensive

- \* Many, many approaches have been proposed to eliminate bounds checks
- \* The IVE-based method shown here is effective for loops whose indices are induction variables
- \* But many programs are not like this

## Dataflow approaches

- \* We can try to use dataflow analysis
- \* lattice elements: pairs  $(lo, hi)$
- \*  $(lo1, hi1) \sqsubseteq (lo2, hi2)$  iff  $lo1 \leq lo2$  and  $hi1 \leq hi2$
- \*  $\perp$  is any  $(x, y)$  where  $x > y$
- \*  $\top$  is  $(-\infty, \infty)$
- \* This is the **range lattice**

## Range lattice

- \* Unfortunately, the range lattice has infinite chains
- \* A typical ad hoc solution is to keep track of the number of updates to any variable during dataflow analysis and then “widen” to  $(-\infty, \infty)$  after  $N$  iterations, for some  $N$

## Arithmetic-based approaches

- \* The dataflow approach is still ignorant of basic rules of arithmetic, however
- \* It is often profitable to analyze the program using a decision procedure for some fragment of arithmetic
- \* We will have some readings on this

## Next week

- \* Partial redundancy elimination (PRE)
- \* Static single assignment form (SSA)
