

Cache Memories

18-213/18-613: Introduction to Computer Systems 10th Lecture, June 6th, 2022

Announcements

- Lab 3 (attacklab) due tomorrow
- Lab 4 (cachelab) out tomorrow
- Homework continues on the usual schedule
- Looking ahead: Midterm is not next week, but the week after
 - Take-home
 - Counts 25% toward midterm grade
 - Counts as a 2x homework toward final grade
 - Dynamic Memory will be covered next week (not VM)
 - By request of TAs, reverting to lecture order vs spring experiment
 - Won't be covered on exam since it makes little sense to do it before malloc lab
 - This will let those who chose start malloc lab before mid-session break
 - Not generally a good idea, but may be best for some

Today

Cache memory organization and operation

Performance impact of caches

- The memory mountain
- Rearranging loops to improve spatial locality
- Using blocking to improve temporal locality

Recall: Locality

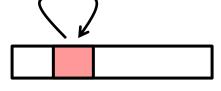

Principle of Locality: Programs tend to use data and instructions with addresses near or equal to those they have used recently

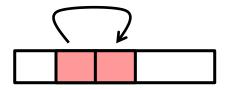

Temporal locality:

 Recently referenced items are likely to be referenced again in the near future

Spatial locality:

 Items with nearby addresses tend to be referenced close together in time

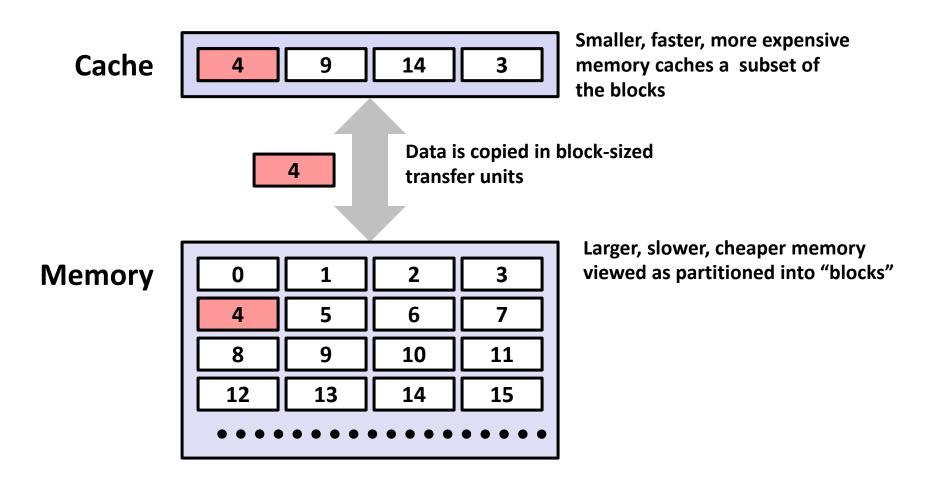

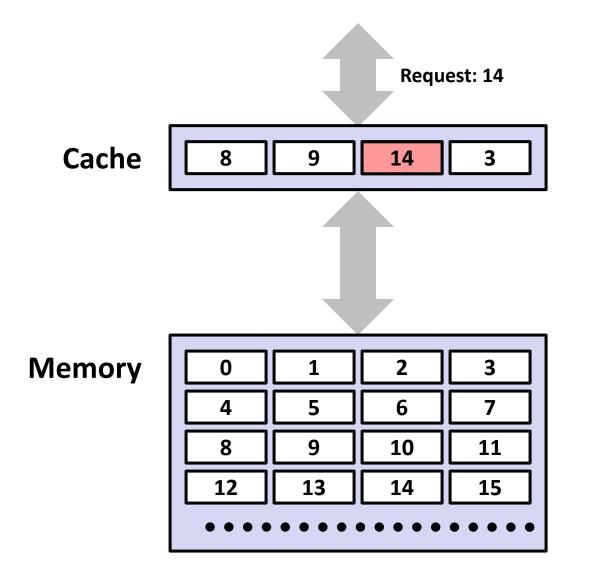

Bryant and O'Hallaron, Computer Systems: A Programmer's Perspective, Third Edition

Recall: General Cache Concepts

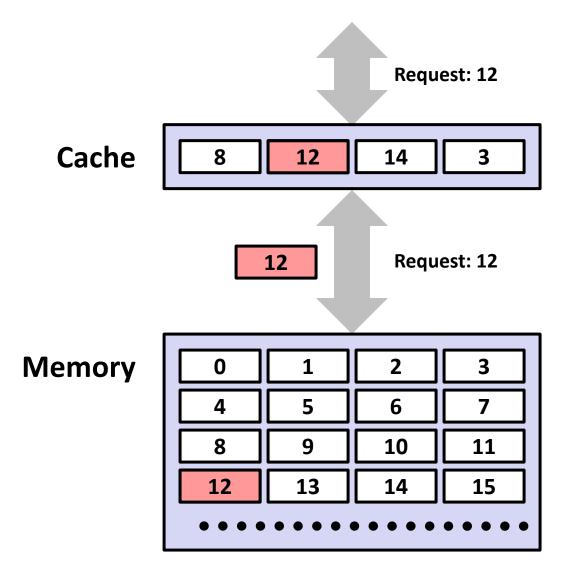

General Cache Concepts: Hit

Data in block b is needed

Block b is in cache: Hit!

General Cache Concepts: Miss

Data in block b is needed

Block b is not in cache: Miss!

Block b is fetched from memory

Block b is stored in cache

- Placement policy: determines where b goes
- Replacement policy: determines which block gets evicted (victim)

Recall: General Caching Concepts: 3 Types of Cache Misses

Cold (compulsory) miss

 Cold misses occur because the cache starts empty and this is the first reference to the block.

Capacity miss

 Occurs when the set of active cache blocks (working set) is larger than the cache.

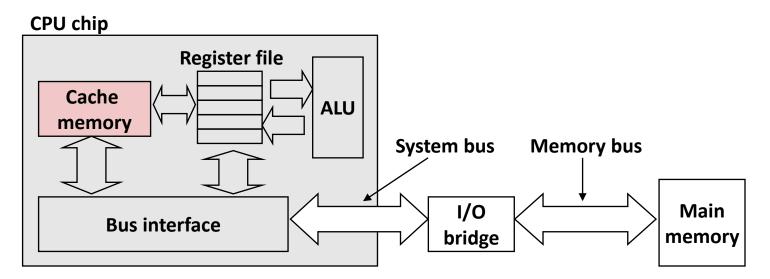

Conflict miss

- Occurs when the cache is large enough, but too many data objects all map (by the placement policy) to the same limited set of blocks
 - E.g., if the placement policy maps both 0 and 8 to the same block, then referencing 0, 8, 0, 8, 0, 8, ... would miss every time.

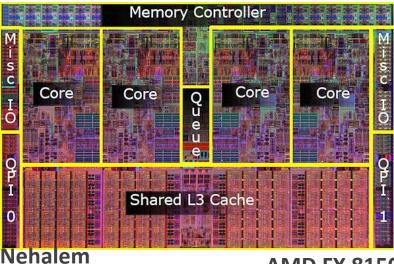

Cache Memories

Cache memories are small, fast SRAM-based memories managed automatically in hardware

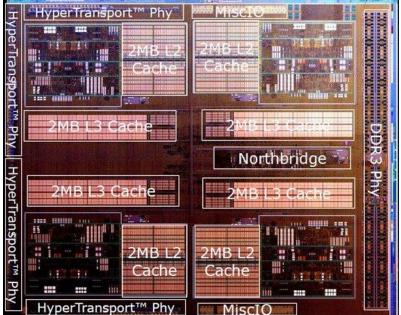

- Hold frequently accessed blocks of main memory
- CPU looks first for data in cache
- Typical system structure:

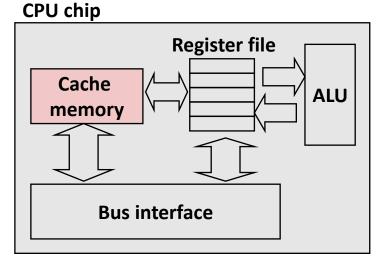

What it Really Looks Like

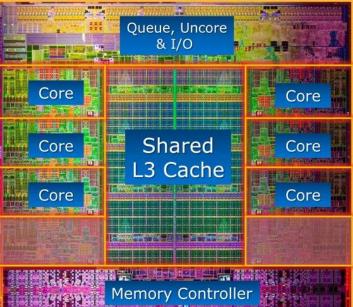

<u>AMD FX 8150</u>

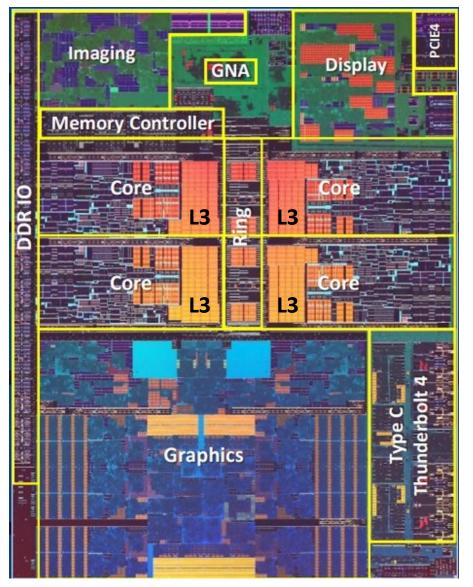

Core i7-3960X

What it Really Looks Like (Cont.)

Bryant and O'Hallaron, Computer Systems: A Programmer's Perspective, Third Edition

Intel Tiger Lake Processor Die (4 core version)

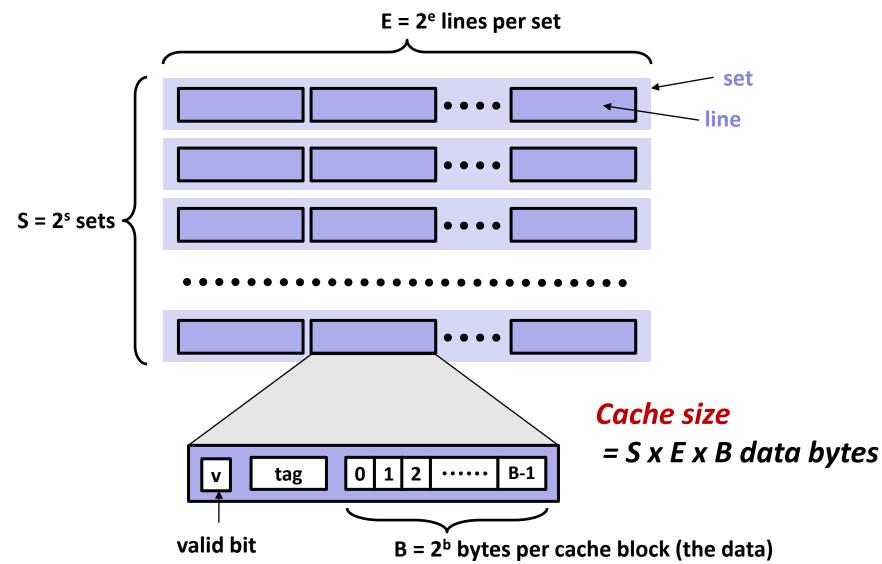

CPU caches

L1 per core: 32KB Instruction + 48KB Data

L2 per core: 1.25MB

Shared L3: 12MB (8 core version has 24MB)

General Cache Organization (S, E, B)

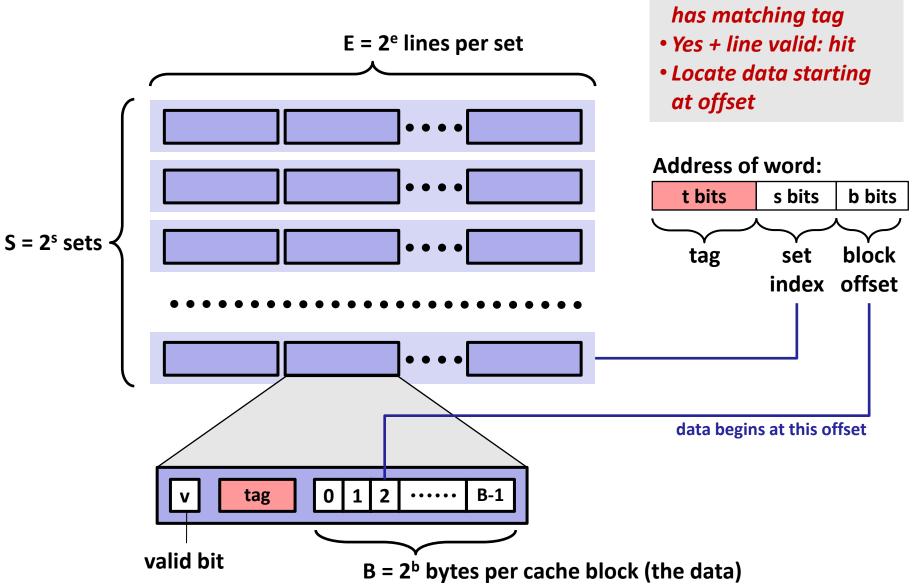

Bryant and O'Hallaron, Computer Systems: A Programmer's Perspective, Third Edition

• Locate set

• Check if any line in set

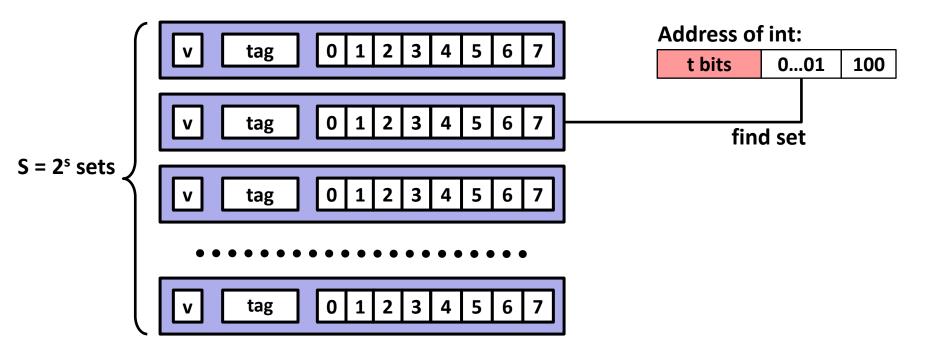

Cache Read

Bryant and O'Hallaron, Computer Systems: A Programmer's Perspective, Third Edition

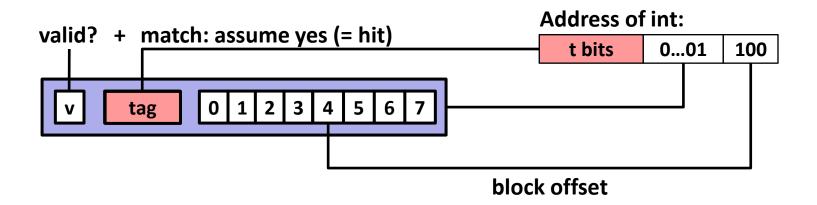

Example: Direct Mapped Cache (E = 1)

Direct mapped: One line per set Assume: cache block size B=8 bytes

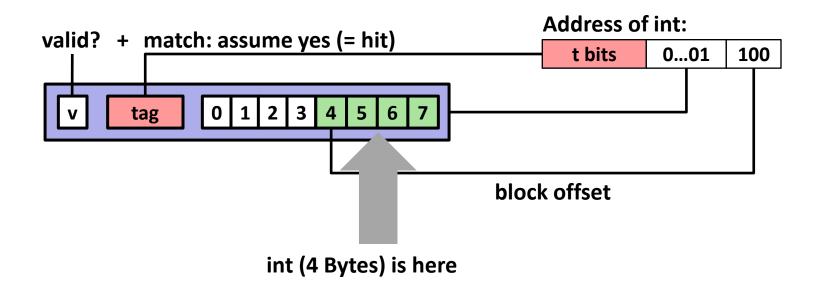

Example: Direct Mapped Cache (E = 1)

Direct mapped: One line per set Assume: cache block size B=8 bytes

Example: Direct Mapped Cache (E = 1)

Direct mapped: One line per set Assume: cache block size B=8 bytes

If tag doesn't match (= miss): old line is evicted and replaced

Direct-Mapped Cache Simulation

| t=1 | s=2 | b=1 |
|-----|-----|-----|
| X | XX | X |

4-bit addresses (address space size M=16 bytes) S=4 sets, E=1 Blocks/set, B=2 bytes/block

Address trace (reads, one byte per read):

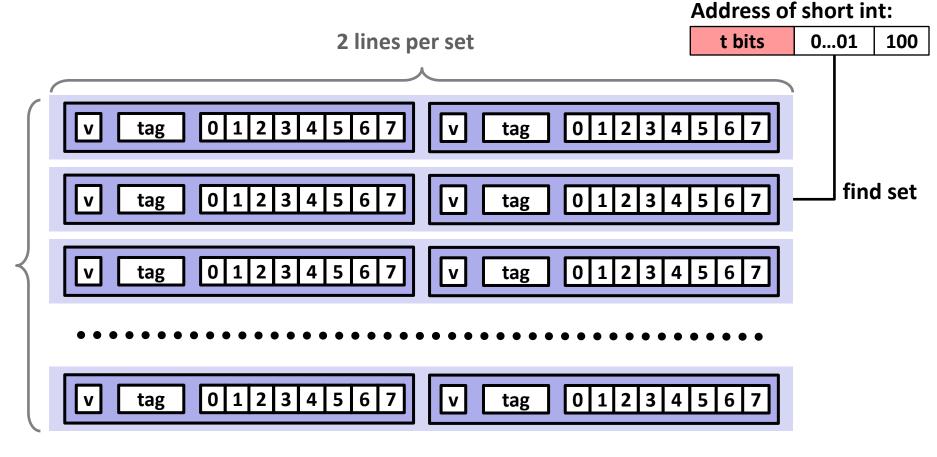

| 0 | [<mark>000</mark> 0 ₂], | miss | (cold) |
|---|--------------------------------------|------|------------|
| 1 | $[0001_{2}],$ | hit | |
| 7 | $[011_2],$ | miss | (cold) |
| 8 | $[1000_{2}],$ | miss | (cold) |
| 0 | [<mark>000</mark> 0 ₂] | miss | (conflict) |

| | V | Tag | Block |
|-------|---|-----|--------|
| Set 0 | 1 | 0 | M[0-1] |
| Set 1 | 0 | | |
| Set 2 | 0 | | |
| Set 3 | 1 | 0 | M[6-7] |

E-way Set Associative Cache (Here: E = 2)

E = 2: Two lines per set

Assume: cache block size B=8 bytes

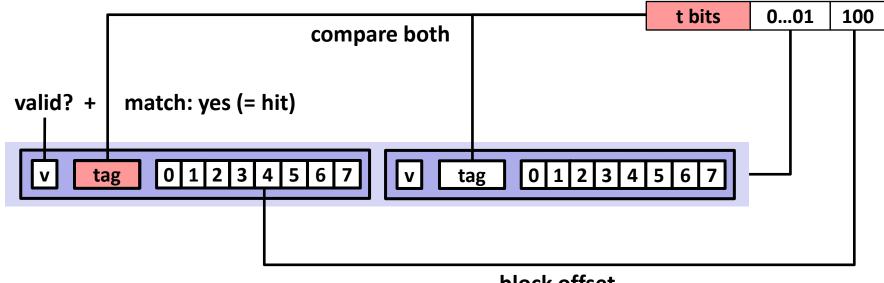

S sets

E-way Set Associative Cache (Here: E = 2)

E = 2: Two lines per set

Assume: cache block size B=8 bytes

Address of short int:

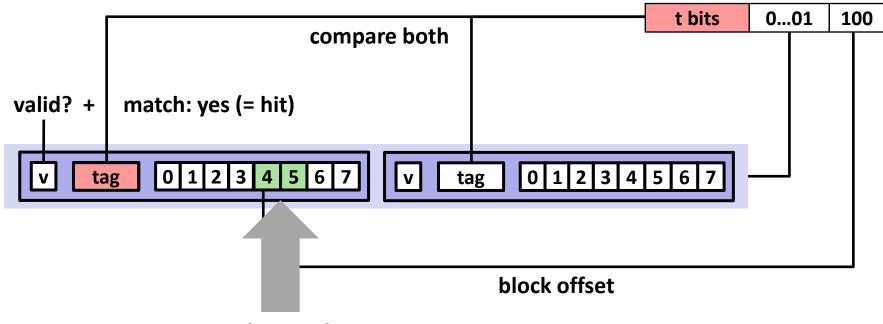

block offset

E-way Set Associative Cache (Here: E = 2)

E = 2: Two lines per set

Assume: cache block size B=8 bytes

Address of short int:

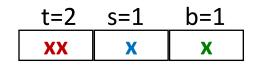

short int (2 Bytes) is here

No match or not valid (= miss):

- One line in set is selected for eviction and replacement
- Replacement policies: random, least recently used (LRU), ...

2-Way Set Associative Cache Simulation

4-bit addresses (M=16 bytes) S=2 sets, E=2 blocks/set, B=2 bytes/block

Address trace (reads, one byte per read):

| 0 | [<mark>000</mark> 0 ₂], | miss |
|---|--------------------------------------|------|
| 1 | [<mark>000</mark> 1 ₂], | hit |
| 7 | [<mark>011</mark> 1 ₂], | miss |
| 8 | [<mark>100</mark> 0 ₂], | miss |
| 0 | [<mark>000</mark> 0 ₂] | hit |

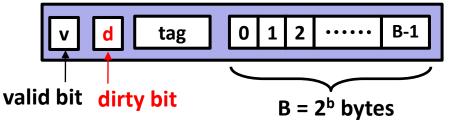

| | v | Tag | Block |
|-------|---|-----|--------|
| Set 0 | 1 | 00 | M[0-1] |
| | 1 | 10 | M[8-9] |
| | | | |
| Set 1 | 1 | 01 | M[6-7] |
| | 0 | | |

What about writes?

- Multiple copies of data exist:
 - L1, L2, L3, Main Memory, Disk
- What to do on a write-hit?
 - Write-through (write immediately to memory)
 - Write-back (defer write to memory until replacement of line)
 - Each cache line needs a dirty bit (set if data differs from memory)

What to do on a write-miss?

- Write-allocate (load into cache, update line in cache)
 - Good if more writes to the location will follow
- No-write-allocate (writes straight to memory, does not load into cache)
- Typical
 - Write-through + No-write-allocate
 - Write-back + Write-allocate

Why Index Using Middle Bits?

Direct mapped: One line per set Assume: cache block size 8 bytes

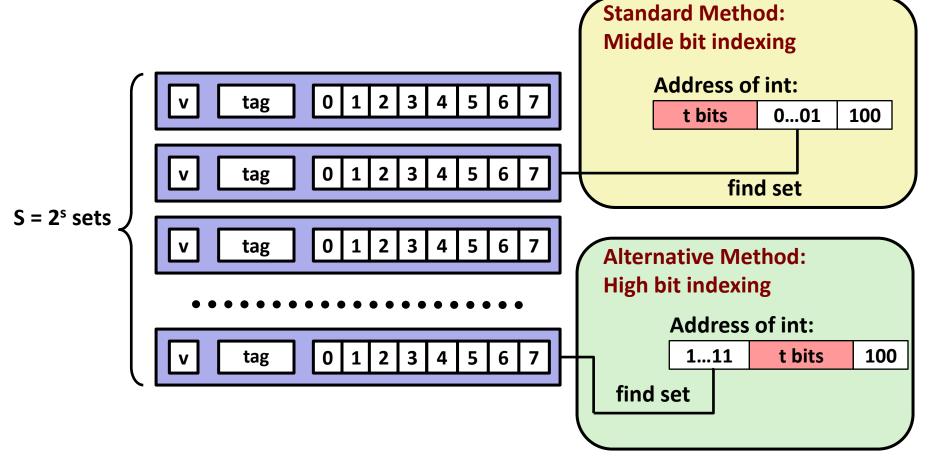

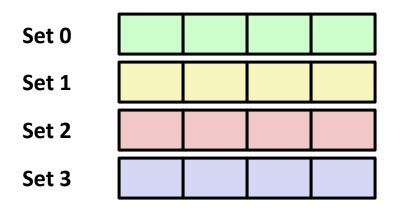

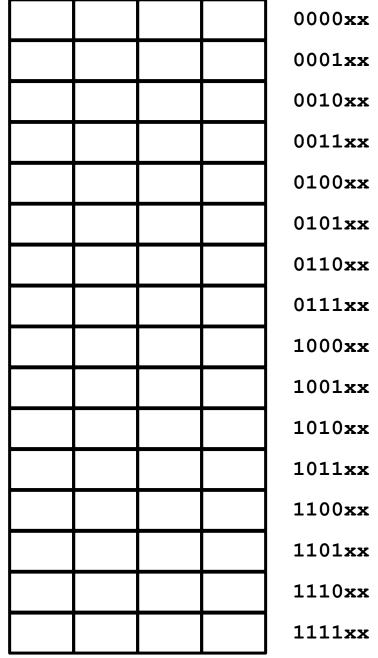

Illustration of Indexing Approaches

- 64-byte memory
 - 6-bit addresses
- 16 byte, direct-mapped cache
- Block size = 4. (Thus, 4 sets; why?)
- 2 bits tag, 2 bits index, 2 bits offset

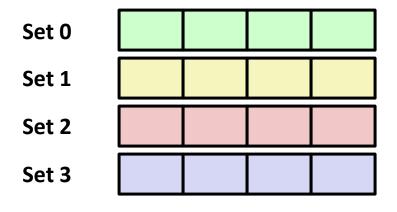

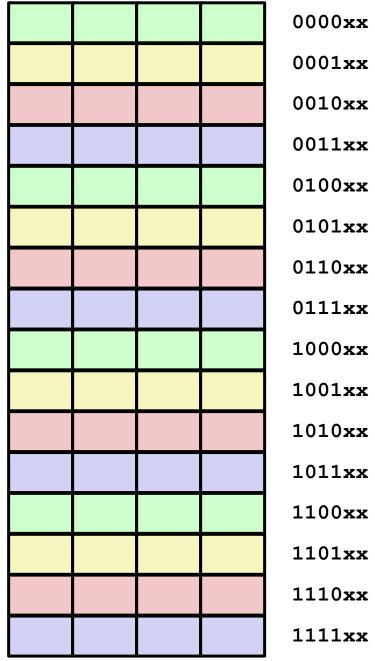

Middle Bit Indexing

Addresses of form TTSSBB

- **TT** Tag bits
- Set index bits
- BB Offset bits
- Makes good use of spatial locality

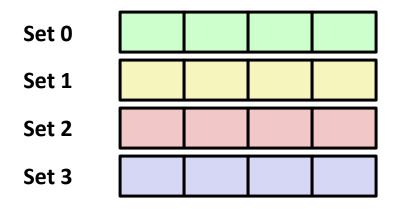

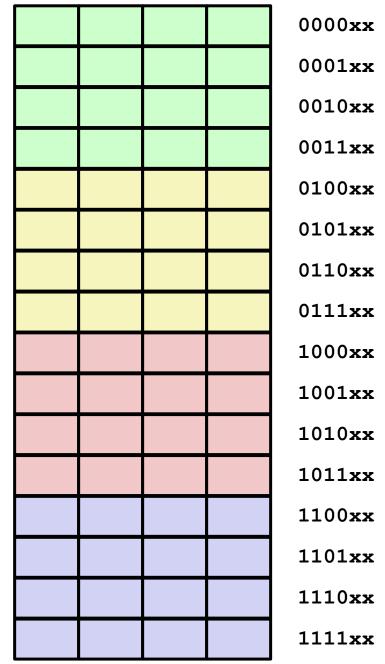

High Bit Indexing

Addresses of form SSTTBB

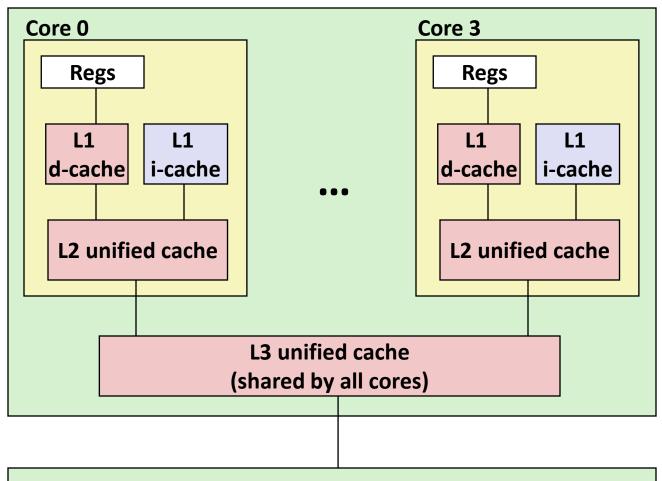

- Set index bits
- **TT** Tag bits
- BB Offset bits
- Program with high spatial locality would generate lots of conflicts

Intel Core i7 Cache Hierarchy

Processor package

Main memory

L1 i-cache and d-cache: 32 KB, 8-way, Access: 4 cycles

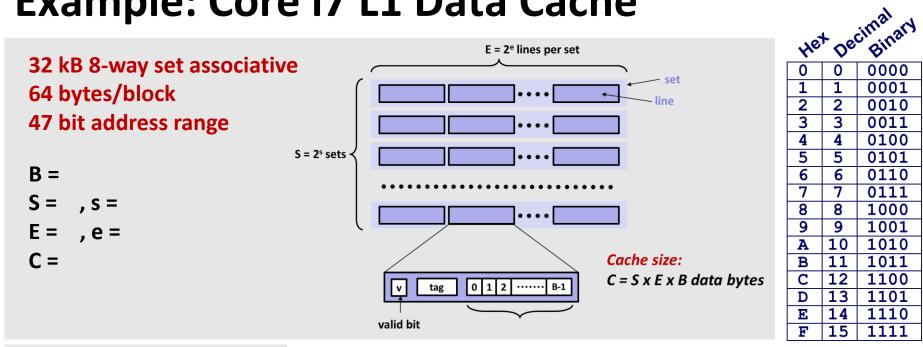

L2 unified cache: 256 KB, 8-way, Access: 10 cycles

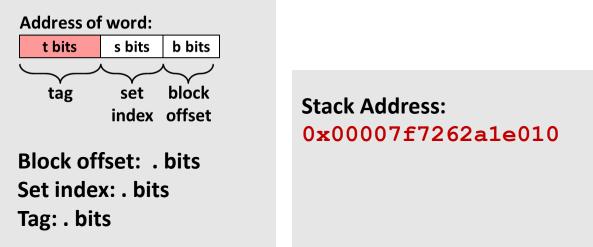

L3 unified cache: 8 MB, 16-way, Access: 40-75 cycles

Block size: 64 bytes for all caches.

Bryant and O'Hallaron, Computer Systems: A Programmer's Perspective, Third Edition

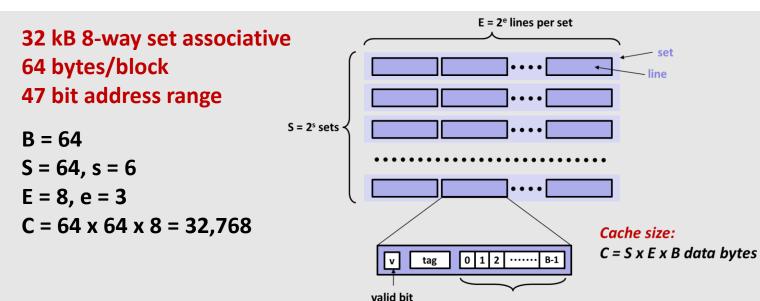

Example: Core i7 L1 Data Cache

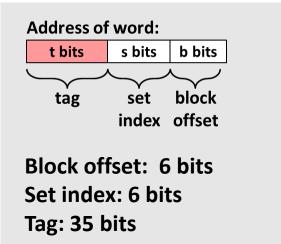

| Block offset: | 0x?? |
|----------------------|------|
| Set index: | 0x?? |
| Tag: | 0x?? |

Example: Core i7 L1 Data Cache

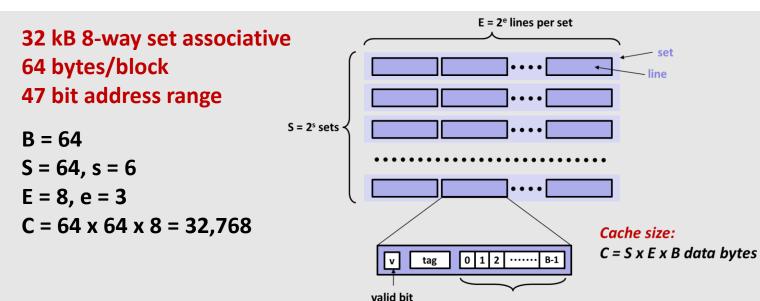

| He | the | Einal Binary 0000 |
|---|---------------------------------|-------------------------|
| | 0 | 0000 |
| 0 1 2 3 4 5 6 7 8 | 1 | 0001 |
| 2 | 1 2 3 4 5 6 7 | 0010 |
| 3 | 3 | 0011 |
| 4 | 4 | 0100 |
| 5 | 5 | 0101 |
| 6 | 6 | 0110 |
| 7 | 7 | 0111 |
| 8 | 8 | 1000 |
| 9 | 9 | 1001 |
| A | 10 | 1010 |
| В | 11 | 1011 |
| B C D | 12 | 1100 |
| D | 13 | 1101 |
| E | 14 | 1110 |
| F | 15 | 1111 |

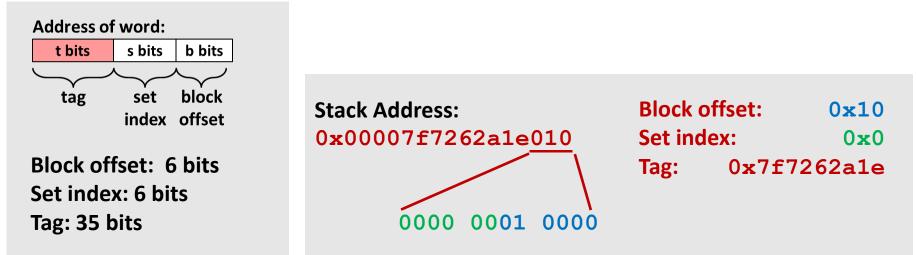

| Stack Address: | Block offset: | 0x?? |
|--------------------|----------------------|--------------|
| 0x00007f7262a1e010 | Set index: | 0x ?? |
| | Tag: | 0x?? |

Example: Core i7 L1 Data Cache

| | He | t Der | cimal Binary |
|---|----------------------------|------------------|--------------|
| Γ | 0 | 0 | 0000 |
| Γ | 1 | 1 | 0001 |
| Γ | 0 1 2 3 | 1 2 3 | 0010 |
| | 3 | 3 | 0011 |
| Γ | 4 5 6 7 8 9 | 4 | 0100 |
| | 5 | 5 6 7 8 | 0101 |
| Γ | 6 | 6 | 0110 |
| Γ | 7 | 7 | 0111 |
| Γ | 8 | 8 | 1000 |
| | | 9 | 1001 |
| Γ | Α | 10 | 1010 |
| Γ | В | 11 | 1011 |
| | B C D | 12 | 1100 |
| | D | 13 | 1101 |
| Γ | Е | 14 | 1110 |
| | F | 15 | 1111 |

Bryant and O'Hallaron, Computer Systems: A Programmer's Perspective, Third Edition

Cache Performance Metrics

Miss Rate

- Fraction of memory accesses not found in cache (misses / accesses)
 = 1 hit rate
- Typical numbers (as %):
 - 3-10% for L1
 - can be quite small (e.g., < 1%) for L2, depending on size, etc.

Hit Time

- Time to deliver a cached block to the processor
 - includes time to determine whether line is in cache
- Typical numbers:
 - 4 clock cycle for L1
 - 10 clock cycles for L2

Miss Penalty

- Additional time required because of a miss
 - typically 50-200 cycles for main memory (Trend: increasing!)

How Bad Can a Few Cache Misses Be?

Huge difference between a hit and a miss

Could be 100x, if just L1 and main memory

Would you believe 99% hits is twice as good as 97%?

- Consider this simplified example: cache hit time of 1 cycle miss penalty of 100 cycles
- Average access time:

97% hits: 1 cycle + 0.03 x 100 cycles = **4 cycles**

99% hits: 1 cycle + 0.01 x 100 cycles = 2 cycles

This is why "miss rate" is used instead of "hit rate"

Writing Cache Friendly Code

Make the common case go fast

Focus on the inner loops of the core functions

Minimize the misses in the inner loops

- Repeated references to variables are good (temporal locality)
- Stride-1 reference patterns are good (spatial locality)

Key idea: Our qualitative notion of locality is quantified through our understanding of cache memories

Canvas > Day 10 – Cache Memories

Bryant and O'Hallaron, Computer Systems: A Programmer's Perspective, Third Edition

Today

Cache organization and operation

Performance impact of caches

- The memory mountain
- Rearranging loops to improve spatial locality
- Using blocking to improve temporal locality

The Memory Mountain

- Read throughput (read bandwidth)
 - Number of bytes read from memory per second (MB/s)
- Memory mountain: Measured read throughput as a function of spatial and temporal locality.
 - Compact way to characterize memory system performance.

Memory Mountain Test Function

```
long data[MAXELEMS]; /* Global array to traverse */
/* test - Iterate over first "elems" elements of
          array "data" with stride of "stride",
 *
 *
          using 4x4 loop unrolling.
 */
int test(int elems, int stride) {
    long i, sx2=stride*2, sx3=stride*3, sx4=stride*4;
    long acc0 = 0, acc1 = 0, acc2 = 0, acc3 = 0;
    long length = elems, limit = length - sx4;
    /* Combine 4 elements at a time */
    for (i = 0; i < limit; i += sx4) {</pre>
        acc0 = acc0 + data[i];
        acc1 = acc1 + data[i+stride];
        acc2 = acc2 + data[i+sx2];
       acc3 = acc3 + data[i+sx3];
    }
    /* Finish any remaining elements */
    for (; i < length; i++) {</pre>
        acc0 = acc0 + data[i];
    return ((acc0 + acc1) + (acc2 + acc3));
                               mountain/mountain.c
```

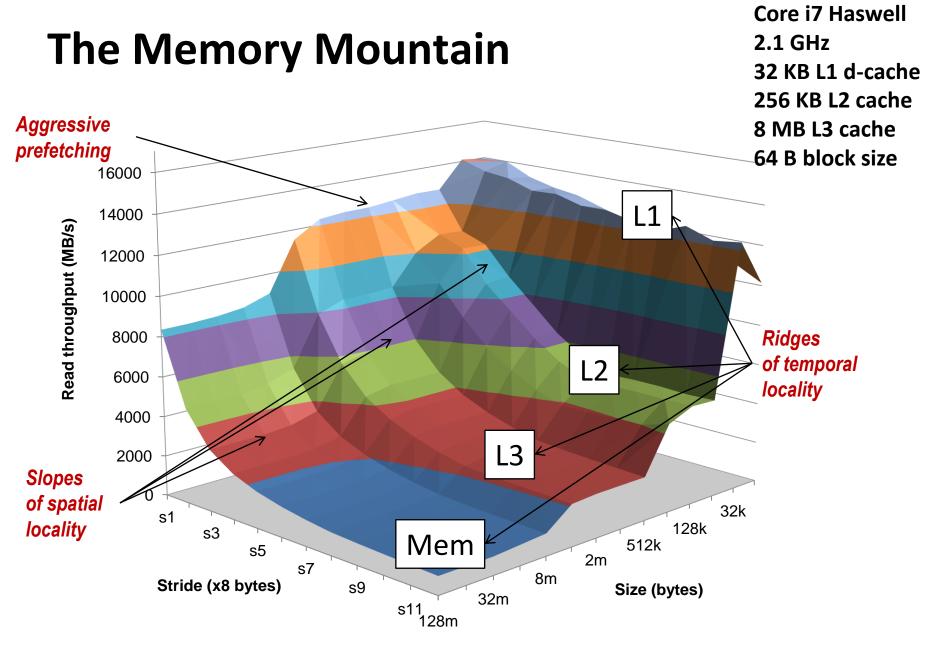

Call test() with many combinations of elems and stride.

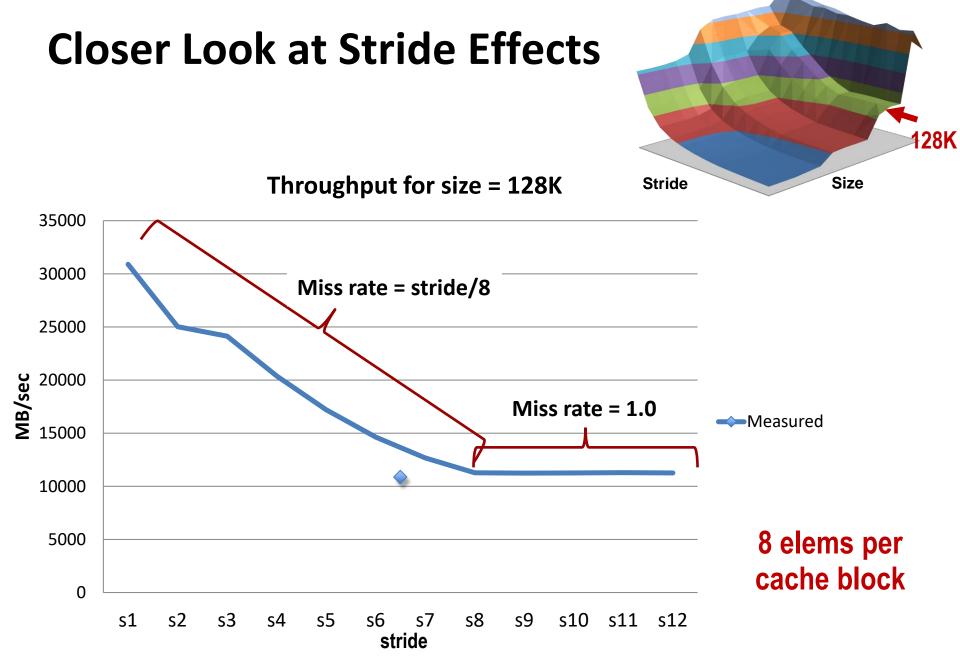

For each elems and stride:

1. Call test() once to warm up the caches.

2. Call test() again and measure the read throughput(MB/s)

Bryant and O'Hallaron, Computer Systems: A Programmer's Perspective, Third Edition

Today

- Cache organization and operation
- Performance impact of caches
 - The memory mountain
 - Rearranging loops to improve spatial locality
 - Using blocking to improve temporal locality

Matrix Multiplication Example

Description:

- Multiply N x N matrices
- Matrix elements are doubles (8 bytes)
- O(N³) total operations
- N reads per source element
- N values summed per destination
 - but may be able to hold in register

/* ijk */ Variable sum held in register for (i=0; i<n; i++) { for (j=0; j<n; j++) { sum = 0.0; { for (k=0; k<n; k++) sum += a[i][k] * b[k][j]; c[i][j] = sum; } } matmult/mm.c

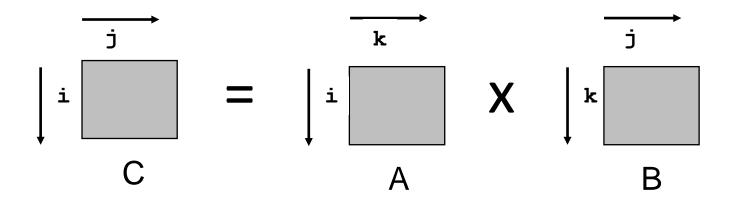

Miss Rate Analysis for Matrix Multiply

Assume:

- Block size = 32B (big enough for four doubles)
- Matrix dimension (N) is very large
 - Approximate 1/N as 0.0
- Cache is not even big enough to hold multiple rows

Analysis Method:

Look at access pattern of inner loop

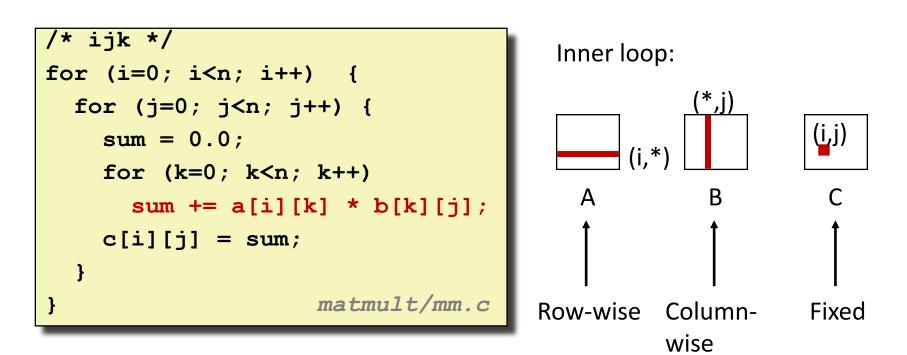

Layout of C Arrays in Memory (review)

- C arrays allocated in row-major order
 - each row in contiguous memory locations
- Stepping through columns in one row:

sum += a[0][i];

- accesses successive elements
- if block size (B) > sizeof(a_{ii}) bytes, exploit spatial locality
 - miss rate = sizeof(a_{ii}) / B
- Stepping through rows in one column:
 - for (i = 0; i < n; i++)
 sum += a[i][0];</pre>
 - accesses distant elements
 - no spatial locality!
 - miss rate = 1 (i.e. 100%)

Matrix Multiplication (ijk)

Miss rate for inner loop iterations:

| <u>A</u> | <u>B</u> | <u>C</u> |
|----------|----------|----------|
| 0.25 | 1.0 | 0.0 |

Block size = 32B (four doubles)

Matrix Multiplication (jik)

```
/* jik */
for (j=0; j<n; j++) {
  for (i=0; i<n; i++) {
    sum = 0.0;
    for (k=0; k<n; k++)
        sum += a[i][k] * b[k][j];
        c[i][j] = sum
    }
}    matmult/mm.c</pre>
```

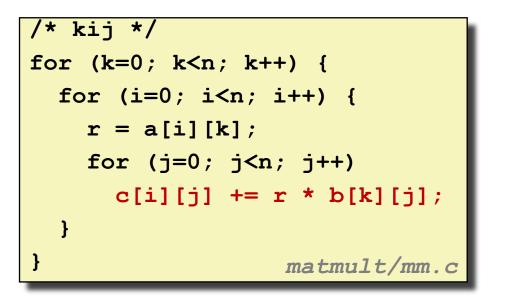

Inner loop: $(i,*) \qquad (i,*) \qquad (j,j) \qquad$

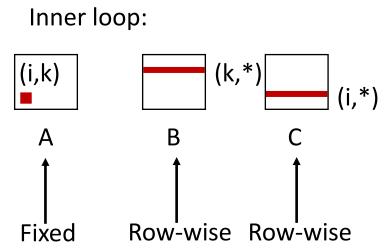

| <u>Misses per inn</u> | er loop ite | eration: | | |
|-----------------------|-------------|----------|--|--|
| <u>A</u> | <u>B</u> | <u>C</u> | | |
| 0.25 | 1.0 | 0.0 | | |
| Same analysis as ijk | | | | |

Block size = 32B (four doubles)

Bryant and O'Hallaron, Computer Systems: A Programmer's Perspective, Third Edition

Matrix Multiplication (kij)

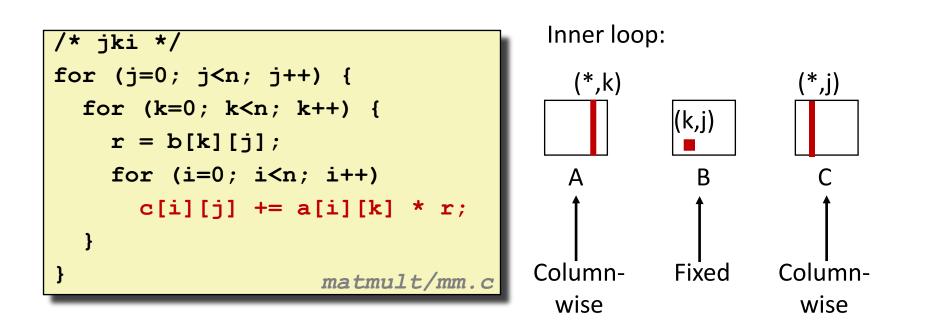

Miss rate for inner loop iterations:ABC0.00.250.25

Block size = 32B (four doubles)

Matrix Multiplication (jki)

$\begin{array}{c|c} \underline{\text{Miss rate for inner loop iterations:}} \\ \underline{A} & \underline{B} & \underline{C} \\ 1.0 & 0.0 & 1.0 \end{array}$

Block size = 32B (four doubles)

Summary of Matrix Multiplication

```
for (i=0; i<n; i++) {
  for (j=0; j<n; j++) {
    sum = 0.0;
    for (k=0; k<n; k++)
        sum += a[i][k] * b[k][j];
    c[i][j] = sum;
  }
}</pre>
```

```
for (k=0; k<n; k++) {
  for (i=0; i<n; i++) {
    r = a[i][k];
    for (j=0; j<n; j++)
      c[i][j] += r * b[k][j];
  }</pre>
```

```
for (j=0; j<n; j++) {
  for (k=0; k<n; k++) {
    r = b[k][j];
    for (i=0; i<n; i++)
      c[i][j] += a[i][k] * r;
}</pre>
```

ijk(&jik):

- 2 loads, 0 stores
- avg misses/iter = 1.25

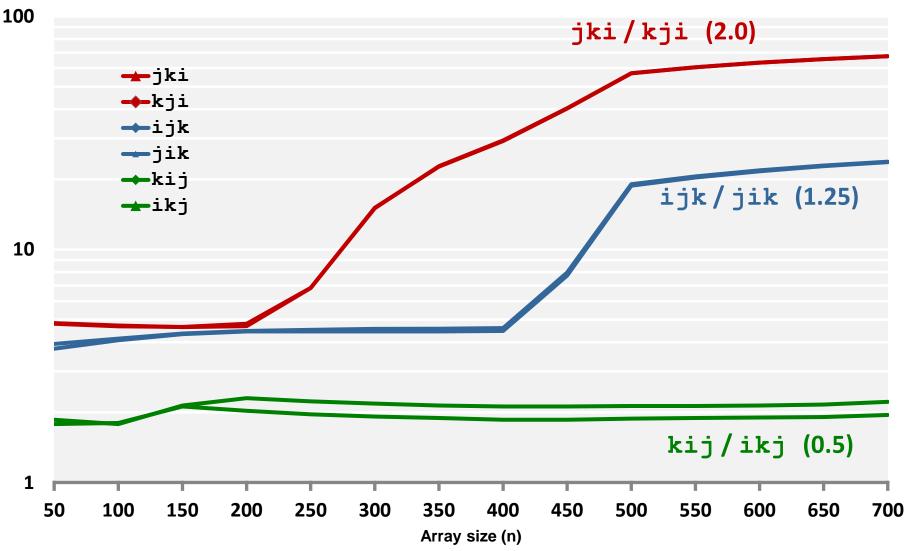

```
kij (& ikj):
    2 loads, 1 store
    avg misses/iter = 0.5
```

jki (& kji):

- 2 loads, 1 store
- avg misses/iter = 2.0

Core i7 Matrix Multiply Performance

Cycles per inner loop iteration

Bryant and O'Hallaron, Computer Systems: A Programmer's Perspective, Third Edition

Today

- Cache organization and operation
- Performance impact of caches
 - The memory mountain
 - Rearranging loops to improve spatial locality
 - Using blocking to improve temporal locality

Example: Matrix Multiplication

```
c = (double *) calloc(sizeof(double), n*n);
/* Multiply n x n matrices a and b */
void mmm(double *a, double *b, double *c, int n) {
    int i, j, k;
    for (i = 0; i < n; i++)
        for (j = 0; j < n; j++)
            for (k = 0; k < n; k++)
                c[i*n + j] += a[i*n + k] * b[k*n + j];
}
j</pre>
```

С

Cache Miss Analysis

Assume:

- Matrix elements are doubles
- Cache line = 8 doubles
- Cache size C << n (much smaller than n)</p>

Bryant and O'Hallaron, Computer Systems: A Programmer's Perspective, Third Edition

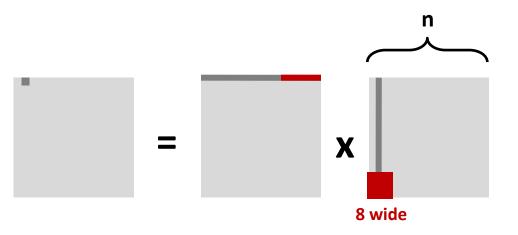

Cache Miss Analysis

Assume:

- Matrix elements are doubles
- Cache line = 8 doubles
- Cache size C << n (much smaller than n)</p>

Second iteration:

Again:
 n/8 + n = 9n/8 misses

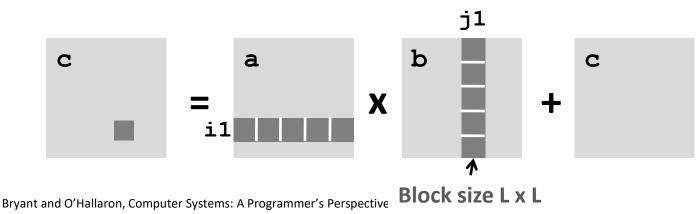

Total misses:

• $9n/8 n^2 = (9/8) n^3$

Blocked Matrix Multiplication

```
c = (double *) calloc(sizeof(double), n*n);
/* Multiply n x n matrices a and b */
void mmm(double *a, double *b, double *c, int n) {
    int i, j, k;
    for (i = 0; i < n; i+=L)
       for (j = 0; j < n; j+=L)
             for (k = 0; k < n; k+=L)
                /* L x L mini matrix multiplications */
                  for (i1 = i; i1 < i+L; i1++)
                      for (j1 = j; j1 < j+L; j1++)
                          for (k1 = k; k1 < k+L; k1++)
                              c[i1*n+j1] += a[i1*n + k1]*b[k1*n + j1];
                                                         matmult/bmm.c
```

Cache Miss Analysis

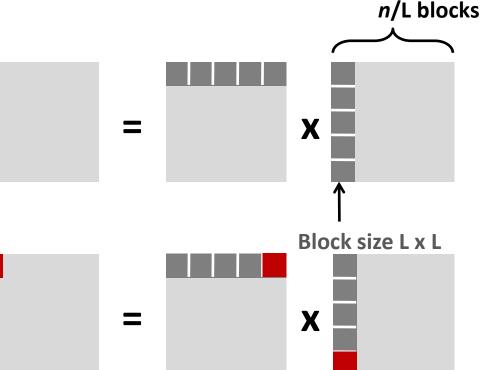

Assume:

- Cache line = 8 doubles. Blocking size $L \ge 8$
- Cache size C << n (much smaller than n)
- Three blocks fit into cache: 3L² < C</p>

First (block) iteration:

- Misses per block: L²/8
- Blocks per Iteration: 2n/L (omitting matrix c)
- Misses per Iteration:
 2n/L x L²/8 = nL/4
- Afterwards in cache (schematic)

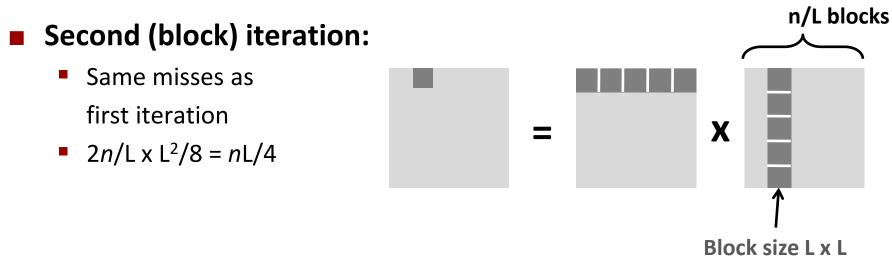

Cache Miss Analysis

Assume:

- Cache line = 8 doubles. Blocking size $L \ge 8$
- Cache size C << n (much smaller than n)
- Three blocks fit into cache: 3L² < C</p>

Total misses:

• nL/4 misses per iteration x $(n/L)^2$ iterations = $n^3/(4L)$ misses

Blocking Summary

- No blocking: (9/8) n³ misses
- Blocking: (1/(4L)) n³ misses

Use largest block size L, such that L satisfies 3L² < C</p>

Fit three blocks in cache! Two input, one output.

Reason for dramatic difference:

- Matrix multiplication has inherent temporal locality:
 - Input data: $3n^2$, computation $2n^3$
 - Every array elements used O(n) times!
- But program has to be written properly

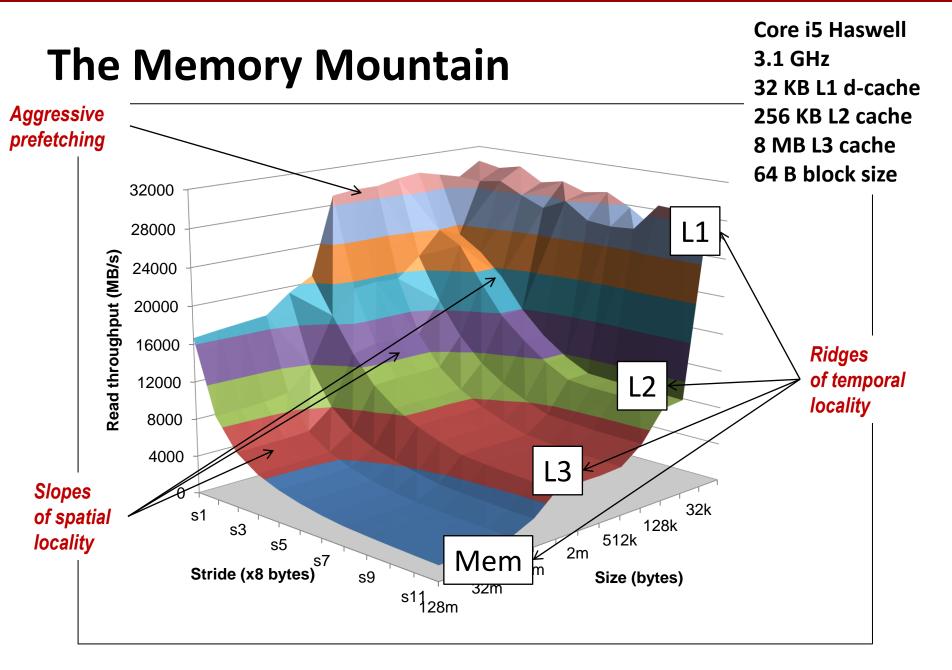

Cache Summary

Cache memories can have significant performance impact

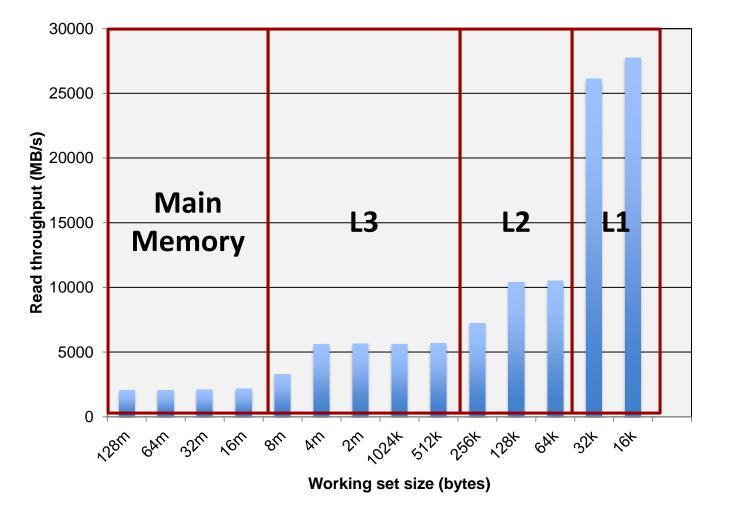

You can write your programs to exploit this!

- Focus on the inner loops, where bulk of computations and memory accesses occur.
- Try to maximize spatial locality by reading data objects sequentially with stride 1.
- Try to maximize temporal locality by using a data object as often as possible once it's read from memory.
