

## 15-499: Algorithms and Applications

Data Compression V - Compressing Graphs  
- The Blanford-Blelloch-Kash Algorithm

15-499

Page 1

## Compression Outline

**Introduction:** Lossy vs. Lossless, Benchmarks, ...

**Information Theory:** Entropy, etc.

**Probability Coding:** Huffman + Arithmetic Coding

**Applications of Probability Coding:** PPM + others

**Lempel-Ziv Algorithms:** LZ77, gzip, compress, ...

**Other Lossless Algorithms:** Burrows-Wheeler

**Lossy algorithms for images:** JPEG, MPEG, ...

➡ **Compressing graphs and meshes:** BBK

15-499

Page 2

## Compressing Structured Data

So far we have concentrated on Text and Images, compressing sound is also well understood.

What about various forms of "structured" data?

- Web indexes
- Triangulated meshes used in graphics
- Maps (mapquest on a palm)
- XML
- Databases

15-499

Page 3

## Compressing Graphs

**Goal:** To represent large graphs compactly while supporting queries efficiently

- e.g., adjacency and neighbor queries

Applications:

- Large web graphs
- Large meshes
- Phone call graphs

15-499

Page 4

## Results

$O(n)$ -bit compression on "separable graphs" with  $n$  vertices, with  $O(1)$  access time

Experimental results:

- 6-12 bits/edge in total
- access time faster than linked-list representation

15-499

Page 5

## Vertex Separators

A vertex separator for  $G=(V,E)$  is a set of vertices  $U \subset V$ , that partitions  $V/U$  into two components  $V_1$  and  $V_2$

A class of graphs  $S$  satisfies a  $f(n)$ -vertex separator theorem if

- $\exists \alpha < 1, \beta > 0$
- $\forall (V,E) \in S, \exists$  separator  $U,$
- $|U| < \beta f(|V|),$
- $|V_i| < \alpha |V|, i = 1,2$

A separable class of graphs is one that satisfies an  $n^c$ -separator theorem,  $c < 1$ .

15-499

Page 6

## Edge Separators

An edge separator for  $(V,E)$  is a set of edges  $E' \subset E$  whose removal partitions  $V$  into two components  $V_1$  and  $V_2$

A class of graphs  $S$  satisfies a  $f(n)$ -edge separator theorem if

- $\exists \alpha < 1, \beta > 0$
- $\forall (V,E) \in S, \exists$  separator  $E',$
- $|E'| < \beta f(|V|),$
- $|V_i| < \alpha |V|, i = 1,2$

Any class of graphs that satisfies an edge separator theorem satisfies the corresponding vertex separator theorem as well.

15-499

Page 7

## Separable Classes of Graphs

Planar graphs:  $O(n^{1/2})$  separators

Well-shaped meshes in  $R^d$ :  $O(n^{1-1/d})$  [Miller et al.]

Nearest-neighbor graphs

In practice, good separators from circuit graphs, street graphs, web connectivity graphs, router connectivity graphs

Note: All separable classes of graphs have bounded density ( $m$  is  $O(n)$ )

15-499

Page 8

## Main Ideas

### For good edge separators

- Number vertices using separators
- Use difference coding on adjacency lists
- Using efficient data structure for indexing

### For good vertex separators

- Each vertex assigned multiple labels
- Separate "root-find" data structure to map labels to a representative
- For adjacency queries, may need to direct graph

15-499

Page 9

## Compressed Adjacency Tables

#	D	Neighbors	Differences
0	2	3 4	3 1
1	4	4 5 6 8	3 1 1 2
2	1	6	4
3	2	0 7	-3 7
4	4	0 1 7 8	-4 1 6 1
5	3	1 6 8	-4 5 2
6	3	1 2 5	-5 1 3
7	3	3 4 8	-4 1 4
8	4	1 4 5 7	-7 3 1 2

15-499

Page 10

## Compressed Adjacency Tables

#	D	Neighbors	Differences
0	1	1	1
1	3	0 2 3	-1 2 1
2	3	1 3 4	-1 2 1
3	4	1 2 4 5	-1 1 2 1
4	4	2 3 5 6	-2 1 2 1
5	4	3 4 6 7	-2 1 2 1
6	3	4 5 8	-2 1 3
7	2	5 8	-2 3
8	2	6 7	-2 1

15-499

Page 11

## Log-sized Codes

**Log-sized code:** Any prefix code that takes

$O(\log(d))$  bits to represent an integer  $d$ .

*Gamma code, delta code, skewed Bernoulli code*

**Example: Gamma code**

Prefix: unary code for  $\lfloor \log d \rfloor$

Suffix: binary code for  $d - 2^{\lfloor \log d \rfloor}$

(binary code for  $d$ , except leading

1 is implied)

Decimal	Gamma
1	1
2	010
3	011
4	00100
5	00101
6	00110
7	00111
8	0001000

15-499

Page 12

## Difference Coding

For each vertex, encode:

- Degree
- Sign of first entry
- Differences in adjacency list

#	D	Differences
0	2	3 1

010 0 011 1  
degree sign 3 1

#	D	Differences
4	4	-4 1 6 1

00100 1 00100 1 00110 1  
degree sign 4 1 6 1

Concatenate vertex encodings to encode the graph

## Indexing

**Problem:** We need to find the start of a vertex quickly.

**Formally:** Given  $n$  numbers in range  $1..O(n)$ , prepare a data structure that returns the  $k^{\text{th}}$  smallest number.

Can be supported with  $O(n)$  bits and  $O(1)$  access time.

## Renumbering with Edge Separators

## Renumbering with Edge Separators

## Renumbering with Edge Separators

15-499

Page 17

## Renumbering with Edge Separators

15-499

Page 18

## Theorem (edge separators)

Any class of graphs that allows  $O(n^c)$  edge separators can be compressed to  $O(n)$  bits with  $O(1)$  access time using:

- Difference coded adjacency lists
- $O(n)$ -bit indexing structure

15-499

Page 19

## Proof Outline

Bound cost of adjacency lists: cost of edge  $(a,b)$  is at most  $O(\log(|a-b|))$

If an edge is a separator in a graph of size  $d$ , then its cost is at most  $\log(d)$

$n^c$  edges in separator: cost  $n^c \log(n)$

$$T(n) = n^c \log(n) + 2T(n/2) = O(n)$$

15-499

time is for one DFS

ge 23

## Conclusions

$O(n)$ -bit representation of separable graphs with  $O(1)$ -time queries  
Space efficient and fast in practice for a wide variety of graphs.

15-499

Page 24

## Compression Summary

Compression is all about **probabilities**

We want the model to skew the probabilities as much as possible (*i.e.*, decrease the **entropy**)

15-499

Page 25

## Compression Summary

How do we figure out the probabilities

- Transformations that skew them
  - Guess value and code difference
  - Move to front for temporal locality
  - Run-length
  - Linear transforms (Cosine, Wavelet)
  - Renumber (graph compression)
- Conditional probabilities
  - Neighboring context

In practice one almost always uses a combination of techniques

15-499

Page 26
