

15-499: Algorithms and Applications

- Error Correcting Codes II
- Cyclic Codes
 - Reed-Solomon Codes

15-499

Page 1

Reed-Solomon: Outline

A $(n, k, n-k+1)$ Reed Solomon Code:

Consider the polynomial

$$p(x) = a_{k-1}x^{k-1} + \dots + a_1x + a_0$$

Message: $(a_{k-1}, \dots, a_1, a_0)$

Codeword: $(p(1), p(2), \dots, p(n))$

To keep the $p(i)$ fixed size, we use $a_i \in GF(p^r)$

To make the $p(i)$ distinct, $n < p^r$

Any subset of size k of $(p(1), p(2), \dots, p(n))$ is enough to reconstruct $p(x)$.

15-499

Page 2

Reed Solomon: Outline

A $(n, k, 2s+1)$ Reed Solomon Code:

Can **detect** $2s$ errors

Can **correct** s errors

Generally can correct α erasures and β errors if
 $\alpha + 2\beta \leq 2s$

15-499

Page 3

Reed Solomon: Outline

Correcting s errors:

1. Find $k + s$ symbols that agree on a polynomial $p(x)$.
These must exist since originally $k + 2s$ symbols agreed and only s are in error
2. There are no $k + s$ symbols that agree on the wrong polynomial $p'(x)$
 - Any subset of k symbols will define $p'(x)$
 - Since at most s out of the $k+s$ symbols are in error, $p'(x) = p(x)$

15-499

Page 4

Reed Solomon: Outline

Systematic version of Reed-Solomon

$$p(x) = a_{k-1} x^{k-1} + \dots + a_1 x + a_0$$

Message: $(a_{k-1}, \dots, a_1, a_0)$

Codeword: $(a_{k-1}, \dots, a_1, a_0, p(1), p(2), \dots, p(2s))$

This has the advantage that if we know there are no errors, it is trivial to decode.

Later we will see that version of RS used in practice uses something slightly different than $p(1), p(2), \dots$

This will allow us to use the "**Parity Check**" ideas from linear codes (i.e. $Hc^T = 0$) to quickly test for errors.

15-499

Page 5

RS in the Real World

(204,188,17)₂₅₆ : ITU J.83(A)²

(128,122,7)₂₅₆ : ITU J.83(B)

(255,223,33)₂₅₆ : Common in Practice

- Note that they are all byte based (i.e. symbols are from $GF(2^8)$).

Performance on 600MHz Pentium (approx.):

- (255,251) = 45Mbps
- (255,223) = 4Mbps

Dozens of companies sell hardware cores that operate 10x faster (or more)

- (204,188) = 320Mbps (Altera decoder)

15-499

Page 6

Applications of Reed-Solomon Codes

- **Storage:** CDs, DVDs, "hard drives",
- **Wireless:** Cell phones, wireless links
- **Satellite and Space:** TV, Mars rover, ...
- **Digital Television:** DVD, MPEG2 layover
- **High Speed Modems:** ADSL, DSL, ..

Good at handling burst errors.

Other codes are better for random errors.

- e.g. Gallager codes, Turbo codes

15-499

Page 7

RS and "burst" errors

Let's compare to Hamming Codes (which are "optimal").

	code bits	check bits
RS (255, 253, 3) ₂₅₆	2040	16
Hamming (2¹¹-1, 2¹¹-11-1, 3) ₂	2047	11

They can both correct 1 error, but not 2 random errors.

- The Hamming code does this with fewer check bits
- However, RS can fix 8 contiguous bit errors in one byte
- Much better than lower bound for 8 arbitrary errors

$$\log \left(1 + \binom{n}{1} + \dots + \binom{n}{8} \right) > 8 \log(n-7) \approx 88 \text{ check bits}$$

15-499

Page 8

Discrete Fourier Transform

Another View of Reed-Solomon Codes

α is a primitive n^{th} root of unity ($\alpha^n = 1$) - a generator

$$T = \begin{pmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & \alpha & \alpha^2 & \dots & \alpha^{n-1} \\ 1 & \alpha^2 & \alpha^4 & \dots & \alpha^{2(n-1)} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & \alpha^{n-1} & \alpha^{2(n-1)} & \dots & \alpha^{(n-1)(n-1)} \end{pmatrix} \begin{pmatrix} c_0 \\ \vdots \\ c_{k-1} \\ c_k \\ \vdots \\ c_{n-1} \end{pmatrix} = T \cdot \begin{pmatrix} m_0 \\ \vdots \\ m_{k-1} \\ 0 \\ \vdots \\ 0 \end{pmatrix}$$

$m = T^{-1}c$
Inverse DFT

The Discrete
Fourier Transform
(DFT)

15-499

Page 9

DFT Example

$\alpha = x$ is 7th root of unity in $GF(2^3)/x^3 + x + 1$

(ie, multiplicative group, which excludes additive inverse)

Recall $\alpha = "2", \alpha^2 = "3", \dots, \alpha^7 = 1 = "1"$

$$T = \begin{pmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & \alpha & \alpha^2 & \alpha^3 & \alpha^4 & \alpha^5 & \alpha^6 \\ 1 & \alpha^2 & \alpha^4 & \alpha^6 & & & \\ 1 & \alpha^3 & \alpha^6 & & & & \\ 1 & \alpha^4 & & \ddots & & & \\ 1 & \alpha^5 & & & \ddots & & \\ 1 & \alpha^6 & & & & \ddots & \end{pmatrix} = \begin{pmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 2 & 2^2 & 2^3 & 2^4 & 2^5 & 2^6 \\ 1 & 3 & 3^2 & 3^3 & & & \\ 1 & 4 & 4^2 & & & & \\ 1 & 5 & & \ddots & & & \\ 1 & 6 & & & \ddots & & \\ 1 & 7 & & & & \ddots & \end{pmatrix} \begin{matrix} m_0 \\ m_1 \\ m_2 \\ m_3 \\ m_4 \\ m_5 \\ m_6 \end{matrix}$$

Should be clear that $c = T \cdot (m_0, m_1, \dots, m_{k-1}, 0, \dots)^T$
is the same as evaluating $p(x) = m_0 + m_1x + \dots + m_{k-1}x^{k-1}$
at n points.

15-499

Page 10

Decoding

Why is it hard?

Brute Force: try $k+s$ choose $k + 2s$ possibilities and solve for each.

15-499

Page 11

Cyclic Codes

A code is cyclic if:

$$(c_0, c_1, \dots, c_{n-1}) \in C \Rightarrow (c_{n-1}, c_0, \dots, c_{n-2}) \in C$$

Both **Hamming** and **Reed-Solomon** codes are cyclic.

Note: we might have to reorder the columns to make the code "cyclic".

A linear code is cyclic if its "basis vectors" are cyclic

We will only consider linear cyclic codes.

Motivation: They are more efficient to decode than general codes.

15-499

Page 12

Generator and Parity Check Matrices

Generator Matrix:

A $k \times n$ matrix G such that:

$$C = \{m \bullet G \mid m \in \Sigma^k\}$$

Made from stacking the basis vectors

Parity Check Matrix:

A $(n - k) \times n$ matrix H such that:

$$C = \{v \in \Sigma^n \mid H \bullet v^T = 0\}$$

Codewords are the nullspace of H

These **always exist for linear codes**

For the same code: $H \bullet G^T = 0$

15-499

Page 13

Generator and Parity Check Polynomials

Generator Polynomial:

A degree $(n-k)$ polynomial g such that:

$$C = \{m \bullet g \mid m \in \Sigma^k[x]\}$$

such that $g \mid x^n - 1$

Parity Check Polynomial:

A degree k polynomial h such that:

$$C = \{v \in \Sigma^n[x] \mid h \bullet v = 0 \pmod{x^n - 1}\}$$

such that $h \mid x^n - 1$

These **always exist for linear cyclic codes**

For the same code: $h \bullet g = x^n - 1$

15-499

Page 14

Viewing g as a matrix

If $g = g_0 + g_1x + \dots + g_{n-k}x^{n-k}$

We can put this generator in matrix form:

$$G = \begin{pmatrix} g_0 & g_1 & \dots & g_{n-k} & 0 & \dots & 0 \\ 0 & g_0 & \dots & g_{n-k-1} & g_{n-k} & \dots & 0 \\ \vdots & & \ddots & & & \ddots & \vdots \\ 0 & 0 & \dots & g_0 & g_1 & \dots & g_{n-k} \end{pmatrix}$$

Write $m = m_0 + m_1x + \dots + m_{k-1}x^{k-1}$ as $(m_0, m_1, \dots, m_{k-1})$

Then $c = mG$

15-499

Page 15

g generates cyclic codes

$$G = \begin{pmatrix} g_0 & g_1 & \dots & g_{n-k} & 0 & \dots & 0 \\ 0 & g_0 & \dots & g_{n-k-1} & g_{n-k} & \dots & 0 \\ \vdots & & \ddots & & & \ddots & \vdots \\ 0 & 0 & \dots & g_0 & g_1 & \dots & g_{n-k} \end{pmatrix} = \begin{pmatrix} g \\ xg \\ \vdots \\ x^{k-1}g \end{pmatrix}$$

Codes are linear combinations of the rows.

All but last row is clearly cyclic (based on next row)

Shift of last row is $x^k g \pmod{x^n - 1}$

Consider $h = h_0 + h_1x + \dots + h_kx^k$ ($gh = x^n - 1$)

$$h_0g + (h_1x)g + \dots + (h_{k-1}x^{k-1})g + (h_kx^k)g = x^n - 1$$

$$x^k g = -h_k^{-1}(h_0g + h_1(xg) + \dots + h_{k-1}(x^{k-1}g)) \pmod{x^n - 1}$$

This is a linear combination of the rows.

15-499

Page 16

Viewing h as a matrix

If $h = h_0 + h_1x + \dots + h_kx^k$

we can put this parity check poly. in matrix form:

$$H = \begin{pmatrix} 0 & \dots & 0 & h_k & \dots & h_1 & h_0 \\ 0 & \dots & h_k & h_{k-1} & \dots & h_0 & 0 \\ \vdots & \ddots & & & \ddots & & \vdots \\ h_k & \dots & h_1 & h_0 & 0 & \dots & 0 \end{pmatrix}$$

$$Hc^T = 0$$

15-499

Page 17

Hamming Codes Revisited

The Hamming $(7,4)_2$ code.

$$g = 1 + x + x^3 \qquad h = x^4 + x^2 + x + 1$$

$$G = \begin{pmatrix} 1 & 1 & 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 1 & 0 & 1 \end{pmatrix} \qquad H = \begin{pmatrix} 0 & 0 & 1 & 0 & 1 & 1 & 1 \\ 0 & 1 & 0 & 1 & 1 & 1 & 0 \\ 1 & 0 & 1 & 1 & 1 & 0 & 0 \end{pmatrix}$$

$$gh = x^7 - 1, \quad GH^T = 0$$

The columns are not identical to the previous example Hamming code.

15-499

Page 18

Factors of $x^n - 1$

These define the cyclic codes of length n.

Lets say $x^n - 1$ can be factored into 4 irreducible polynomials.

$$\text{- i.e } x^n - 1 = p_1(x)p_2(x)p_3(x)p_4(x)$$

How many cyclic codes of length n are there?

15-499

Page 19

$g(x)$ when $\Sigma = GF(p^r)$ and $n = p^r$

Let α be a **generator** of $GF(p^r)$.

Let $n = p^r - 1$ (the size of the multiplicative group)

Then $g(x) = (x - \alpha)(x - \alpha^2) \dots (x - \alpha^{n-k})$

is a generator polynomial.

Lemma: $g \mid x^n - 1$ ($a \mid b$, means a divides b)

Proof:

- $\alpha^n = 1$ (because of the size of the group)

$$\Rightarrow \alpha^n - 1 = 0$$

$$\Rightarrow \alpha \text{ root of } x^n - 1$$

$$\Rightarrow (x - \alpha) \mid x^n - 1$$

- similarly for $\alpha^2, \alpha^3, \dots, \alpha^{n-k}$

- therefore $x^n - 1$ is divisible by $(x - \alpha)(x - \alpha^2) \dots$

15-499

Page 20

Back to Reed-Solomon

Consider a generator polynomial $g \in GF(p^n)[x]$, s.t. $g \mid (x^n - 1)$
 Recall that $n - k = 2s$ (the degree of g)

Encode:

- $m' = m x^{2s}$ (basically shift by $2s$)
- $b = m' \pmod{g}$
- $c = m' - b = (m_{k-1}, \dots, m_0, -b_{2s-1}, \dots, -b_0)$
- Note that c is a **cyclic code** based on g
 - $m' = qg + b$
 - $c = m' - b = qg$

Parity check:

- $hc = 0?$

Example

Lets consider the $(7,3,5)_8$ Reed-Solomon code.
 We use $GF(2^3)/x^3 + x + 1$

α	x	010	2
α^2	x^2	100	3
α^3	$x + 1$	011	4
α^4	$x^2 + x$	110	5
α^5	$x^2 + x + 1$	111	6
α^6	$x^2 + 1$	101	7
α^7	1	001	1

Example RS (7,3,5)₈

$$g = (x - \alpha)(x - \alpha^2)(x - \alpha^3)(x - \alpha^4)$$

$$= x^4 + \alpha^3x^3 + x^2 + \alpha x + \alpha^3$$

$$h = (x - \alpha^5)(x - \alpha^6)(x - \alpha^7)$$

$$= x^3 + \alpha^3x^3 + \alpha^2x + \alpha^4$$

$$gh = x^7 - 1$$

Consider the message: 110 000 110

$$m = (\alpha^4, 0, \alpha^4) = \alpha^4x^2 + \alpha^4$$

$$m' = x^4m = \alpha^4x^6 + \alpha^4x^4$$

$$= (\alpha^4x^2 + x + \alpha^3)g + (\alpha^3x^3 + \alpha^6x + \alpha^6)$$

$$c = (\alpha^4, 0, \alpha^4, \alpha^3, 0, \alpha^6, \alpha^6)$$

$$= 110\ 000\ 110\ 011\ 000\ 101\ 101 \quad ch = 0 \pmod{x^7 - 1}$$

α	010
α^2	100
α^3	011
α^4	110
α^5	111
α^6	101
α^7	001

A useful theorem

Theorem: For any β , if $g(\beta) = 0$ then $\beta^{2s}m(\beta) = b(\beta)$

Proof:

$$x^{2s}m(x) = g(x)q(x) + d(x)$$

$$\beta^{2s}m(\beta) = g(\beta)q(\beta) + b(\beta) = b(\beta)$$

Corollary: $\beta^{2s}m(\beta) = b(\beta)$ for $\beta \in \{\alpha, \alpha^2, \dots, \alpha^{2s}\}$

Proof:

$\{\alpha, \alpha^2, \dots, \alpha^{2s}\}$ are the roots of g by definition.

Fixing errors

Theorem: Any k symbols from c can reconstruct c and hence m

Proof:

We can write $2s$ equations involving m (c_{n-1}, \dots, c_{2s}) and b (c_{2s-1}, \dots, c_0). These are

$$\alpha^{2s} m(\alpha) = b(\alpha)$$

$$\alpha^{4s} m(\alpha^2) = b(\alpha^2)$$

...

$$\alpha^{2s(2s)} m(\alpha^{2s}) = b(\alpha^{2s})$$

We have at most $2s$ unknowns, so we can solve for them. (I'm skipping showing that the equations are linearly independent).

15-499

Page 25

Efficient Decoding

I don't plan to go into the Reed-Solomon decoding algorithm, other than to mention the steps.

15-499

Page 26
