## Homework 2

---

1. What is an algorithm with the smallest number of comparisons you can find for outputting both the maximum and the minimum of  $n$  numbers?
2. What is an algorithm with the smallest number of comparisons you can find for outputting the  $n^{1/3}$ -ranked item in a list of  $n$  unordered distinct items in the comparison-based model? You can use  $O(\cdot)$ -notation.
3. In class we saw how to find a  $k$ -multiplicative spanner with  $O(n^{1+1/t})$  edges on any unweighted undirected graph  $G$  on  $n$  vertices, where  $k = 2t - 1$ . Suppose now each edge  $e$  of  $G$  has a weight  $w_e$ , and the distance between two nodes  $u$  and  $v$  in  $G$  along a path  $P$  is the sum of weights of the edges along  $P$ . Then  $d_G(u, v)$  is the shortest path distance between  $u$  and  $v$ . Show how to find a subgraph  $H$  of  $G$  which is a  $k$ -multiplicative spanner with  $O(n^{1+1/t})$  edges.
