Abstract

Given a subspace $X \subseteq \mathbb{R}^d$ and a finite set $S \subseteq \mathbb{R}^d$, we introduce the Delaunay simplicial complex, $D_X$, restricted by $X$. Its simplices are spanned by subsets $T \subseteq S$ for which the common intersection of Voronoi cells meets $X$ in a non-empty set. By the nerve theorem, $\bigcup D_X$ and $X$ are homotopy equivalent if all such sets are contractible. This paper shows that $\bigcup D_X$ and $X$ are homeomorphic if the sets can be further subdivided in a certain way so they form a regular CW complex.

1 Introduction

This paper studies the problem of constructing simplicial complexes that represent or approximate a geometric object in some finite-dimensional Euclidean space, $\mathbb{R}^d$. We refer to the geometric object as a topological space or subspace of $\mathbb{R}^d$. This problem arises in geometric modeling and finite element analysis, and it is a special case of the grid generation problem [21]. It is special because we only consider grids or complexes made up of simplices. The problem can be divided into two questions:

- How do we choose the points or vertices of the grid?
- How do we connect the vertices using edges, triangles, and higher-dimensional simplices?

In this paper we concentrate on the second question. In particular, given a subspace and a finite point set in $\mathbb{R}^d$, we give an unambiguous rule for constructing a simplicial complex representing the subspace. Topological properties of this simplicial complex, such as whether its domain is homotopy equivalent or homeomorphic to the subspace, can be studied based on local interactions between the subspace and the Voronoi neighborhoods of the points. This leads us back to the first question: additional points can be chosen so they improve the local interaction patterns. How this can be done in a concrete, possibly three-dimensional setting ought to be the subject of future investigations.

Simplicial complexes and triangulations. An affinely independent point set $T \subseteq \mathbb{R}^d$ defines the simplex $\sigma_T = \text{conv } T$. Its dimension is $k = \dim \sigma_T = \text{card } T - 1$, and it is also referred to as a $k$-simplex. The points of $T$ are the vertices of $\sigma_T$. A simplicial complex, $K$, is a finite collection of simplices that satisfies the following two properties: if $\sigma_T \in K$ and $U \subseteq T$ then $\sigma_U \in K$, and if $\sigma_T, \sigma_V \in K$ then $\sigma_T \cap \sigma_V = \sigma_{T \cap V}$. The first property implies $\emptyset \in K$, and the first and second properties combined imply $\sigma_T \cap \sigma_V \in K$. The vertex set of $K$ is $\text{vert } K = \bigcup_{\sigma \in K} \sigma$, the dimension is $\dim K = \max_{\sigma \in K} \dim \sigma$, and the underlying space is $\bigcup K = \bigcup_{\sigma \in K} \sigma$. A subcomplex of $K$ is a simplicial complex $L \subseteq K$.

A particular simplicial complex defined by a non-degenerate finite set $S \subseteq \mathbb{R}^d$ is the Delaunay simplicial complex, $D = D_S$ [6]. It consists of all simplices $\sigma_T$, $T \subseteq S$, for which there exists an open ball, $B$, with $S \cap \text{cl } B = T$ and $S \cap B = \emptyset$. Given $S$, $D$ is unique, $\dim D = \min\{d, \text{card } S - 1\}$, and $\bigcup D = \text{conv } S$. In computational geometry, $D$ is usually referred to as the Delaunay 'triangulation' of $S$ [7, 18]. To avoid confusion with the topology notion of a triangulation, which is adopted in this paper, we choose to call $D$ a simplicial complex. Following the tradition in combinatorial topology, a triangulation of a topological space $X$ is a simplicial complex $K$ together with a homeomorphism between $X$ and $\bigcup K$ [17, 19]. If there exists a simplicial complex $K$ such that $\bigcup K$ is homeomorphic to $X$, then $X$ is triangulable.

285
Outline. Our approach to constructing a simplicial complex that represents a topological space \( X \subseteq \mathbb{R}^d \) is based on a finite set \( S \subseteq \mathbb{R}^d \) and the Delaunay simplicial complex of this set, \( D = D_S \). Section 2 introduces the concept of a Delaunay simplicial complex \( D_X \) restricted by \( X \), which is a subcomplex of \( D \). This concept is a common generalization of ideas developed by Martinetz and Schulten [15], Chew [4], and Edelsbrunner [8]. \( D_X \) is defined for every \( X \subseteq \mathbb{R}^d \) and every non-degenerate finite \( S \subseteq \mathbb{R}^d \). If \( S \) satisfies the assumptions of the nerve theorem, see section 2, then \( \bigcup D_X \) and \( X \) are homotopy equivalent. Section 3 presents some topological concepts and discusses the meaning of non-degeneracy in detail. Sections 4 and 5 study conditions on \( S \) that guarantee \( \bigcup D_X \) be homeomorphic to \( X \). An explicit construction of a homeomorphism is also given. Section 6 mentions directions for further research.

2 Restricted Delaunay Simplicial Complexes

Coverings and nerves. Let \( X \subseteq \mathbb{R}^d \) be a topological space and \( S \subseteq \mathbb{R}^d \) a finite point set. We assume non-degenerate position of the points in \( S \), which generically means that anything vanishing under a slight perturbation of the points is precluded. For example, we require that \( T \subseteq S \) be affinely independent if card \( T \leq d + 1 \), and that no \( d + 2 \) points of \( S \) be cospherical. Further particulars of this assumption will be discussed in section 3. The Voronoi cell of \( p \in S \) is

\[
V_p = \{ x \in \mathbb{R}^d \mid |xp| \leq |qx|, \quad q \in S \},
\]

where \(|xp|\) denotes the Euclidean distance between points \( y, z \in \mathbb{R}^d \). The collection of Voronoi cells is \( V = V_S = \{ V_p \mid p \in S \} \) [22]. The Voronoi cell restricted to \( X \) of \( p \in S \) is \( V_{p,X} = X \cap V_p \), and the collection of restricted Voronoi cells is \( V_X = V_{S,X} = \{ V_{p,X} \mid p \in S \} \). For a subset \( T \subseteq S \) we have corresponding subsets \( V_T = \{ V_p \mid p \in T \} \subseteq V \) and \( V_{T,X} = \{ V_{p,X} \mid p \in T \} \subseteq V_X \). We will consider their common intersections, \( \bigcap V_T \) and \( \bigcap V_{T,X} = X \cap \bigcap V_T \).

A covering of \( X \) is a collection \( C \) of subsets of \( X \) so that \( X = \bigcup C \). It is a closed (open) covering if each set in \( C \) is closed (open), and it is a finite covering if \( C \) is finite. For a subset \( \mathcal{D} \subseteq C \) consider the common intersection, \( \bigcap \mathcal{D} \). The nerve of a finite covering \( C \) is

\[
\text{nerve } C = \{ \mathcal{D} \subseteq C \mid \bigcap \mathcal{D} \neq \emptyset \}.
\]

We remark that the nerve can be defined for a finite covering of any abstract set, not just for subsets of \( \mathbb{R}^d \). A geometric realization of nerve \( C \) is a simplicial complex, \( \mathcal{K} \), together with a bijection \( \beta \) between \( C \) and the vertex set of \( \mathcal{K} \), so that \( D \subseteq \text{nerve } C \) iff the simplex spanned by \( \beta(D) \) is in \( \mathcal{K} \).

Observe that the collection of Voronoi cells restricted to \( X \), \( V_X \), is a finite closed covering of \( X \). The Delaunay simplicial complex restricted by \( X \), \( D_X = D_{S,X} \), is the geometric realization of nerve \( V_X \) defined by \( \beta(V_p) = p \), for all \( p \in S \). That is, \( D_X = \{ \sigma_T \mid T \subseteq S, \bigcap V_{T,X} \neq \emptyset \} \). Note that \( D_X \) is a subcomplex of the Delaunay simplicial complex \( D = D_S \) of \( S \). See figure 2.1 for an example. The nerve theorem of combinatorial topology

![Figure 2.1: (a) The Voronoi cells of ten points decompose three spaces, \( X_1, X_2, \) and \( X_3 \). (b) The three corresponding Delaunay simplicial complexes consist of an edge, a cycle of three edges, and two triangles sharing an edge, respectively.](image)

[2, 13, 23] sheds some light on the relationship between \( X, V_X \), and \( D_X \). See section 3 for a formal definition of homotopy equivalence and contractibility.

**Theorem (nerve).** Let \( C \) be a finite closed covering of a triangulable space \( X \subseteq \mathbb{R}^d \) so that for every \( D \subseteq C \), \( \bigcap D \) is either empty or contractible. Let \( \mathcal{K} \) be a geometric realization of nerve \( C \). Then \( X \) and \( \bigcup \mathcal{K} \) are homotopy equivalent.

In particular, if \( \bigcap D \) is empty or contractible for every \( D \subseteq V_X \) then \( X \) and \( \bigcup D_X \) are homotopy equivalent.

**Related earlier work.** Martinetz and Schulten [15] study neural nets modeling a topological space \( X \). In geometric language, a neural net consists of finitely many points and edges between them. The algorithm in [15] constructs the net by choosing a finite set \( S \subseteq X \) and selecting edges based on points sampled from \( X \) found in Voronoi cells associated with point pairs. A cell is associated with every pair \( \{p, q\} \subseteq S \) for which \( V_p \cap V_q \neq \emptyset \), see [7, 18]. This cell can be interpreted as a "thickened" version of the face common to \( V_p \) and \( V_q \), and a point of \( X \) sampled in this cell is taken as evidence that \( X \cap V_p \cap V_q \neq \emptyset \). Martinetz and Schulten call the resulting net the induced Delaunay triangulation of \( S \) and \( X \); in the limit it is the same as the edge-skeleton of \( D_X \).
Chew [4] introduces a method for constructing a simplicial complex approximating a (two-dimensional) surface in $\mathbb{R}^3$. Let $X$ be such a surface and $S \subseteq X$ a finite point set. Three points $p, q, r \in S$ span a triangle in the approximating complex if they lie on the boundary of an open ball $B \subseteq \mathbb{R}^2$ with center in $X$ so that $S \cap B = \emptyset$. Assuming non-degeneracy, such a ball $B$ exists if $X \cap V_p \cap V_q \cap V_r \neq \emptyset$. Chew's method can thus be seen as a special case of our definition of restricted Delaunay simplicial complexes.

Finally, Edelsbrunner [8] defines the dual complex of a union of balls in $\mathbb{R}^d$. Consider the case where all balls are equally large. Let $S \subseteq \mathbb{R}^d$ be a finite point set, and define $X = \{x \in \mathbb{R}^d \mid \min_{s \in S} |xp| \leq \rho\}$, for some fixed positive $\rho \in \mathbb{R}$. The Voronoi cells of $S$ decompose $X$ into closed convex regions, and the dual complex is defined as the nerve of these regions, geometrically realized by the map $\beta(p,x) = p$, for all $p \in S$. We see that it is the same as the Delaunay simplicial complex, $D_X$, restricted by $X$. The common intersection of any subset of these regions is convex and therefore contractible, so the nerve theorem implies that the underlying space of the dual complex is homotopy equivalent to $X$.

3 Some Topological Concepts

Neighborhoods, homotopies, homeomorphisms, and manifolds. An open ball in $\mathbb{R}^d$ is a set $B = B(x, \rho) = \{y \in \mathbb{R}^d \mid |yx| < \rho\}$ for some point $x \in \mathbb{R}^d$ and some positive $\rho \in \mathbb{R}$; $x$ is the center and $\rho$ the radius of $B$. For $Y \subseteq X$, a neighborhood of $Y$ in $X$ is an open subset of $X$ that contains $Y$.

Let $X$ and $Y$ be two topological spaces. Two maps $f, g : X \to Y$ are homotopic if there is a continuous map $h : X \times [0,1] \to Y$ with $h(x,0) = f(x)$ and $h(x,1) = g(x)$ for all $x \in X$. The two spaces, $X$, and $Y$, are homotopy equivalent if there are continuous maps $f : X \to Y$ and $g : Y \to X$ so that $g \circ f$ is homotopic to the identity map in $X$ and $f \circ g$ is homotopic to the identity map in $Y$. $X$ is contractible if it is homotopy equivalent to a point.

Topological spaces $X$ and $Y$ are homeomorphic, written $X \cong Y$, if there is a bijective map $\varphi : X \to Y$ so that $\varphi$ and $\varphi^{-1}$ are continuous. $\varphi$ is a homeomorphism between $X$ and $Y$, and $X$ and $Y$ are homeomorphs of each other. Homeomorphs of open, half-open, and closed balls of various dimensions play an important role in the forthcoming discussions. For $k \geq 0$, let $o$ be the origin of $\mathbb{R}^k$ and define

$$H^k = \{x = (\xi_1, \ldots, \xi_k) \in \mathbb{R}^k \mid \xi_k \geq 0\},$$

$$B^k = \{x \in \mathbb{R}^k \mid |xo| \leq 1\},$$

and

$$S^k = \{x \in \mathbb{R}^k \mid |xo| = 1\}.$$  

For convenience, we define $\mathbb{R}^k = H^k = B^k = S^k = \emptyset$ if $k < 0$. An open $k$-ball is a homeomorph of $\mathbb{R}^k$, a half-open $k$-ball is a homeomorph of $H^k$, a closed $k$-ball is a homeomorph of $B^k$, and a $(k-1)$-sphere is a homeomorph of $S^{k-1}$. For $k \geq 1$ these are disjoint classes of spaces, that is, open balls, half-open balls, closed balls, and spheres are pairwise non-homeomorphic. This is not true for $k = 0$: open, half-open, and closed 0-balls are points, and a 0-sphere is a pair of points.

Our first theorem is about topological spaces that are manifolds, with or without boundary. $X \subseteq \mathbb{R}^d$ is a $k$-manifold without boundary if each $x \in X$ has an open $k$-ball as a neighborhood in $X$. $X \subseteq \mathbb{R}^d$ is a $k$-manifold with boundary if each $x \in X$ has an open or half-open $k$-ball as a neighborhood in $X$, and there is at least one $x \in X$ that has no open $k$-ball as a neighborhood. The set of points without open $k$-ball neighborhood forms the boundary, $\partial X$, of $X$. Note that the boundary of a half-open $k$-ball is an open $(k-1)$-ball, which is therefore without boundary. From this it follows that the boundary of a $k$-manifold with boundary is a $(k-1)$-manifold without boundary. The interior of a manifold $X$ is $\text{int} X = X - \partial X$; it is the set of points with open $k$-ball neighborhoods. Note that our definition distinguishes between manifolds with and without boundary, which is somewhat non-standard as the set of manifolds without boundary is usually considered a subset of the set of manifolds with boundary. A manifold $X$ is compact if every open covering of $X$ has a finite subcovering, or equivalently, if it is closed and bounded. A manifold $Y \subseteq X$ is a submanifold of $X$.

Non-degeneracy. In section 4, we are interested in the intersection between manifolds and affine flats. An $\ell$-manifold $F \subseteq \mathbb{R}^d$ is an $\ell$-flat if it is the affine hull of $\ell+1$ points, or equivalently, it is the intersection of $d-\ell$ hyperplanes, or linear functionals. Let $X \subseteq \mathbb{R}^d$ be an $m$-manifold. Intuitively, a point $x \in X$ has $d$ degrees of freedom, and it loses $d-m$ of them if it is constrained to lie in $X$. Similarly, $x$ losses $d-\ell$ degrees if it is constrained to lie in $F$. So if $x \in X \cap F$ then $x$ should have lost $2d-m-\ell$ degrees of freedom. Hence, $X \cap F$ should be empty if $d-(2d-m-\ell) = m+\ell-d < 0$. In general, we expect $x$ to have $m+\ell-d$ degrees of freedom and $X \cap F$ to be an $(m+\ell-d)$-manifold. Algorithmically, such a non-degeneracy assumption can be simulated by conceptual perturbation techniques, see e.g. [9, 24].

This intuitive argument can be formalized for smooth or piecewise smooth manifolds. We need some definitions from differential topology. For an open set $X \subseteq \mathbb{R}^m$, a map $f : X \to \mathbb{R}^n$ is smooth if it has continuous partial derivatives of all orders and at all points of $X$. For arbitrary $X \subseteq \mathbb{R}^m$, $f$ is smooth if for all $x \in X$ there exists an open ball $B = B(x, \epsilon) \subseteq \mathbb{R}^m$ and a smooth map $g : B \to \mathbb{R}^n$ so that $g$ equals $f$ on $X \cap B$. 

287
Topological spaces $X \subseteq \mathbb{R}^m$ and $Y \subseteq \mathbb{R}^n$ are diffeomorphic if there exists a homeomorphism $\varphi : X \to Y$ so that $\varphi$ and $\varphi^{-1}$ are smooth. An $m$-manifold $X$ with or without boundary is smooth if each $x \in X$ has a neighborhood diffeomorphic to $\mathbb{R}^m$ or $H^k$.

Now, let $X$ be a smooth $m$-manifold, and let $f : X \to \mathbb{R}$ be a smooth map. Then $y \in \mathbb{R}$ is a regular value of $f$ if for every $x \in f^{-1}(y)$ some partial derivative of $f$ at $x$ is non-zero; otherwise, $y$ is a critical value of $f$. By the preimage theorem in differential topology, the preimage of any regular value is a smooth submanifold of $X$ with dimension $m-1$, and by Sard's theorem, the set of critical values has measure 0 in $\mathbb{R}$, see e.g. [10, 11]. This implies that with probability 1, the intersection between a smooth $m$-manifold $X$ and a hyperplane with prescribed normal direction is a smooth $(m-1)$-manifold. Hence, with probability 1, the intersection between $X$ and an $\ell$-flat $F$ with prescribed normal $(d-\ell)$-flat is a smooth $(m+\ell-d)$-manifold. By non-degenerate position of $F$ we mean that this is indeed the case, and it is reasonable to assume non-degenerate position because $F$ just needs to avoid a measure zero set in $\mathbb{R}^{d-\ell}$.

One of the conditions necessary for our results is the non-degeneracy of the intersection between Voronoi cells and the manifold. We thus extend the above notions to Voronoi cells and their intersections. An intersection of Voronoi cells is the common intersection of finitely many closed half-spaces, and thus a convex polyhedron. Let $P$ be a convex polyhedron and let $X$ be a manifold without boundary. We say that $P$ intersects $X$ generically if $X \cap P = \emptyset$ or $X \cap P$ has the right dimension and $X \cap \text{int}P = \text{int}(X \cap P)$. If $X$ is a manifold with boundary, then $P$ intersects $X$ generically if $P$ intersects $\text{int}X$ and $\text{bd}X$ generically. By non-degenerate position of $P$ we mean that $P$ intersects $X$ generically. Again, this is a reasonable assumption to make.

4  Triangulating Compact Manifolds

We are now ready to state conditions under which the restricted Delaunay simplicial complex is a triangulation of $X$. These conditions will be applied only when $X$ is a compact manifold. To avoid any confusion, we note that our results do not settle the open question whether or not all compact manifolds are triangulable.

The closed ball property. Throughout this section we assume non-degenerate position of flats and discrete point sets. Let $m > 0$ and let $X \subseteq \mathbb{R}^d$ be a compact $m$-manifold with or without boundary. Let $S \subseteq \mathbb{R}^d$ be a finite point set. We say that $S$ has the generic intersection property for $X$ if for every subset $T \subseteq S$, $\cap V_T$ intersects $X$ generically. We say that $S$ has the closed ball property for $X$ if for every $\ell \leq m$ and every subset $T \subseteq S$ with $\text{card } T = m + 1 - \ell$, the following two conditions hold:

(B1) $\cap V_{T,X}$ is either empty or a closed $\ell$-ball, and

(B2) $\cap V_{T,\text{bd}X}$ is either empty or a closed $(\ell - 1)$-ball.

In section 3, we argued that it is reasonable to expect $X \cap \cap V_T$ to be an $\ell$-manifold, if $X$ is a smooth $m$-manifold. This is reflected in condition (B1). A similar non-degenerate position assumption is implied by (B2) for the boundary of $X$. We will see that the closed ball property guarantees that dimension is preserved. As an example consider $X_1$ and $\mathcal{D}_X$, in figure 2.1. Condition (B2) is violated by the common edge of the two Voronoi cells intersecting $X_1$. Indeed, $\bigcup \mathcal{D}_{X_1} \neq X_1$ because the dimension of $X_1$ is two and that of $\bigcup \mathcal{D}_{X_1}$ is one.

Two technical lemmas. Before proving the first theorem we establish two facts about the closed ball property. The first says that the closed ball property preserves dimension locally, and the second is a statement about the Voronoi cells intersect a compact manifold and its boundary. We work with arbitrary, that is, possibly non-smooth $m$-manifolds since we do not need any smoothness properties for our proofs. A simplex $\sigma_T \in \mathcal{D}_X$ is a principal simplex if there is no proper superset $U \supset T$ with $\sigma_U \in \mathcal{D}_X$. The first fact is formalized in the following lemma.

Lemma 4.1 (preservation of dimension). Let $m \geq 1$, let $X \subseteq \mathbb{R}^d$ be a compact $m$-manifold with or without boundary, and let $T \subseteq \mathbb{R}^d$ be a non-degenerate finite set of points that has the generic intersection property for $X$. If $S$ has the closed ball property for $X$ then every principal simplex of $\mathcal{D}_X$ is an $m$-simplex.

Proof. Let $\sigma_T \in \mathcal{D}_X$ be a principal simplex, and define $F' = \cap V_T$ and $F = \cap V_{T,X}$. By condition (B1), $F = X \cap F'$ is a closed $\ell$-ball, with $\ell = m + 1 - \text{card } T$. Since $\sigma_T \in \mathcal{D}_X$, we have $F \neq \emptyset$, which implies $\ell \geq 0$ and therefore card $T \leq m + 1$. If card $T = m + 1$ then $\sigma_T$ is an $m$-simplex and we are done. So suppose card $T < m + 1$. Since $\sigma_T$ is a principal simplex, it follows that $F \subseteq \text{int} F'$, for otherwise there is a proper face $G' = \cap V_{T'}$ of $F'$, so $T \subset T'$, with $X \cap G' \neq \emptyset$. If follows that $\sigma_{T'} \in \mathcal{D}_X$, which contradicts the principality of $\sigma_T$.

Finally, we show that $F \subseteq \text{int} F'$ also leads to a contradiction. As mentioned above, $F$ is a closed $\ell$-ball and hence $\text{bd} F$ is an $(\ell - 1)$-sphere. This $(\ell - 1)$-sphere is contained in $\text{int} F'$, so it must lie in $\text{bd} X$. Indeed, $\text{bd} F = \text{bd} X \cap F'$. This contradicts condition (B2), which requires $\text{bd} X \cap F'$ be a closed $(\ell - 1)$-ball. □

For the next lemma we need a classic result on subdivisions of a certain type of complex. A closed ball is
called a cell, or a $k$-cell if its dimension is $k$. A finite collection of non-empty cells, $\mathcal{R}$, is a regular CW complex if the cells have pairwise disjoint interiors, and the boundary of each cell is the union of other cells in $\mathcal{R}$. A subset of $\mathcal{R}$ is a chain if its elements can be ordered so that each contains its predecessors and is contained in its successors. Let $C_{\mathcal{R}}$ be the set of chains in $\mathcal{R}$ and note that nerve $C_{\mathcal{R}}$ is well defined. The result mentioned is that any geometric realization of nerve $C_{\mathcal{R}}$ is homeomorphic to $\bigcup \mathcal{R}$. It can be found in [5, chapter V] and [14, chapter III] and also in [3] where it is applied to manifolds subdivided by the cells of a regular CW complex. Another classic result needed is the weak Schönflies theorem, see e.g. [20, chapter 3], which implies that if $A$ is a piecewise linear $k$-sphere and $B \subset A$ is a piecewise linear closed $k$-ball then $A - \text{int} \, B$ is also a closed $k$-ball.

**Lemma 4.2** (complimentary closed ball property). Let $m$, $X$, and $S$ be as in lemma 4.1. Let $T \subseteq S$ be so that $G = \bigcap_{T \subseteq S} \mathcal{R}_{T, \text{bd}} \neq \emptyset$, and define $F = \bigcap_{T \subseteq U} \mathcal{R}_{T, \text{bd}}$ and $\ell = m - \text{card} \, T$. If $S$ has the closed ball property for $X$, these sets are cells, so $\mathcal{R}$ is a regular CW complex and $F = \bigcup \mathcal{R}$. Let $K$ be a geometric realization of nerve $C_{\mathcal{R}}$ and let $\varphi : F \rightarrow K$ be a homeomorphism; it exists because of the homeomorphism result mentioned above. Note that $\varphi(\text{bd} \, F) = \text{bd} \, K$ is the underlying space of a subcomplex of $K$, and similarly, $\varphi(G) = \text{int} \, K$ for a subcomplex $\mathcal{L} \subset K$. By construction, $\text{bd} \, K = \text{int} \, K$ is a piecewise linear $\ell$-sphere and $\text{int} \, K \subset \text{bd} \, K$ is a piecewise linear closed $\ell$-ball. The weak Schönflies theorem implies that $\text{bd} \, K - \text{int} \, \mathcal{L}$ is a closed $\ell$-ball. Since $\varphi$ is a homeomorphism, $\varphi^{-1}(\text{bd} \, K - \text{int} \, \mathcal{L}) = \text{bd} \, F - \text{int} \, G$ is also a closed $\ell$-ball, as claimed. \hfill $\square$

**Theorem 4.3** Let $X \subseteq \mathbb{R}^d$ be a compact manifold, with or without boundary, and let $S \subseteq \mathbb{R}^d$ be a non-degenerate finite point set that has the generic intersection property for $X$. If $S$ has the closed ball property for $X$ then $\bigcup \mathcal{D}_{\mathcal{X}} \approx X$.

**Proof.** For each $i$, define $V_i = \left\{ \bigcap_{T \subseteq U} \mathcal{R}_{T, \text{bd}} \mid \text{card} \, T = m + 1 - i \right\}$ and note that because of the closed ball property all elements in $V_i$ are closed $i$-balls. We inductively construct simplicial complexes $K_i$ and homeomorphisms $\varphi_i : \bigcup V_i \cup K_i$, so that $K_{i-1} \subseteq K_i$ and $\varphi_i$ agrees with $\varphi_{i-1}$ on $\bigcup V_{i-1}$. When we arrive at $K = K_m$ and $\varphi = \varphi_m$ we show there is a simplicial homeomorphism between $K$ and $\text{sd} \, \mathcal{D}_{\mathcal{X}}$. The result follows because $X = \bigcup V_m \approx \bigcup K \approx \bigcup \text{sd} \, \mathcal{D}_{\mathcal{X}} = \bigcup \mathcal{D}_{\mathcal{X}}$. To start the induction, let each $T \subseteq S$ correspond to a point $v_T$ in $\mathbb{R}^d$. Let $e$ be large enough and choose the points in $\mathbb{R}^d$ so that any collection of simplices of dimension up to $m$ spanned by these points satisfy the properties of a simplicial complex. Define
$K_0 = \{ v_T \mid T \subseteq S, \text{ card } T = m + 1, \bigcap V_T,X \neq \emptyset \}$. At this stage the homeomorphism $\varphi_0 : V_0 \to K_0$ defined by $\varphi_0(G) = \{ v_T \mid \varphi_0(G) = \emptyset \}$ is just a bijection between two finite point sets.

Suppose $0 \leq j \leq m - 1$ and $K_j$ and $\varphi_j : \bigcup V_j \to \bigcup K_j$ are constructed. Let $i = j + 1$ and initialize $K_i = K_j$. Let $T \subseteq S$ with card $T = m + 1 - i$ so that $F = \bigcap V_T,X \neq \emptyset$ and $\varphi_j$ is not yet in $K_i$. Define $G = \bigcap V_T,bd X$. We add simplices to $K_i$ that will allow us to extend the homeomorphism so it includes $F \subseteq V_i$. Specifically, consider all sets $U \subseteq S$, with $T \subseteq U$ and $\bigcap V_U,X \neq \emptyset$. The corresponding simplices $\varphi_j$ belong to $K_j$ and are contained in $\varphi_j(bd F - int G)$. Add all simplices $\varphi_j(V_T,X)$ to $K_i$. To extend the homeomorphism we distinguish two cases. Assume first that $G = \emptyset$, and therefore $F \subseteq int X$. Since $\varphi_j$ is a homeomorphism and $F$ is a closed $i$-ball, $bd F$ and $\varphi_j(bd F)$ are both $(i)$-spheres. It follows that $\bigcup v_T, st \varphi_i$ is a closed $i$-ball, and a homeomorphism $\varphi_i : F \to \bigcup v_T, st \varphi_i$ that agrees with $\varphi_j$ on $bd F$ can be constructed. Now assume $G \neq \emptyset$. By lemma 4.2, $bd F - int G$ and therefore $\varphi_j(bd F - int G)$ are closed $(i)-$balls. Furthermore, $bd G$ is an $(i-2)$-sphere. Let $L \subseteq K_i$ consist of the simplices $\varphi_j(bd G)$, with $\varphi_j \subseteq \varphi_j(bd G)$. $L \subseteq$ is a closed $(i-1)$-ball, and a homeomorphism $\varphi_i : G \to L$ that agrees with $\varphi_j$ on $bd G$ can be established. Now we are in the same situation as in the first case, and a homeomorphism $\varphi_i : F \to \bigcup v_T, st \varphi_i$ that agrees with $\varphi_j$ on $G$ and with $\varphi_j$ on $bd F - int G$ can be constructed. After adding all $F = \bigcap V_T,X$ with card $T = m + 1 - i$ in this fashion, we get $\varphi_i$ by combining all $\varphi_i$ using the pasting lemma.

Observe that $K$ and $sd D_X$ contain a vertex for each $T \subseteq S$ with $\bigcap V_T,X \neq \emptyset$, so $vert sd D_X = \{ b_T \mid \varphi_j \in vert K_i \}$. It follows that $f : vert K \to vert sd D_X$ defined by $f(\varphi_i) = b_T$ is a bijection. By construction of $K_i$, if a collection of vertices belong to a common simplex in $K_i$, then their images belong to a common simplex in $sd D_X$. It follows that the simplicial map $g : \bigcup K \to \bigcup sd D_X$ implied by $f$ is a homeomorphism. Therefore, $\bigcup K \approx \bigcup sd D_X = \bigcup D_X$, and the assertion of the theorem follows.

REMARK. As illustrated in figure 4.1, the Delaunay simplicial complex restricted by $X$ is related to the complex obtained from the chains of the regular CW complex defined by the Voronoi cells. Besides being smaller, an advantage of the Delaunay simplicial complex is that it naturally imbeds in the same space that contains $X$ and $S$.

REMARK. For manifolds of dimension 3 or less, condition (B2) is implied by (B1) and the weaker requirement (B2') $\bigcap V_T,bd X$ is either empty or contractible.

Of course, this is interesting only for manifolds with boundary, for otherwise (B2) and (B2') are void. To see why (B2') is sufficient, let $1 \leq m \leq 3$ and suppose $X$ and $S$ satisfy the assumptions in lemma 4.1. Assume also that $S$ satisfies condition (B1), that is, for every $\ell \leq m$ and every $T \subseteq S$ with card $T = m + 1 - \ell$, $F = \bigcap V_T,X$ is either empty or a closed $\ell$-ball. Note that

$$G = \bigcap V_T,bd X = bd F - \bigcup_{T \subseteq S} \text{int} \bigcap V_T,X$$

is either empty or an $(\ell - 1)$-manifold contained in an $(\ell-1)$-sphere, namely $bd F$. For $\ell \leq 3$, the contractibility of $G \neq \emptyset$ implies that $G$ is a closed $(\ell - 1)$-ball; so (B2') implies (B2).

For $m = 4$, (B2') implies (B2) if the Poincaré conjecture for 3-spheres is true, see e.g. [1].

5 General Topological Spaces

In this section, we generalize the result for compact manifolds to more general topological spaces. The requirements will automatically exclude spaces that cannot be expressed as the underlying space of a finite regular CW complex. In order to generalize theorem 4.3, we need extensions of the generic intersection and the closed ball properties. Let $X \subseteq \mathbb{R}^d$ be a topological space and let $S \subseteq \mathbb{R}^d$ be a non-degenerate finite point set. $S$ has the extended closed ball property for $X$ if there is a regular CW complex $R$, with $X = \bigcup R$, that satisfies the following properties for every $T \subseteq S$ with $\bigcap V_T,X \neq \emptyset$:

(E1) there is a regular CW complex $R_T \subseteq R$ so that $\bigcap V_T,X = \bigcup R_T$,

(E2) the set $R_T = \{ \gamma \in R \mid \text{int } \gamma \subseteq \bigcap V_T,X \}$ contains a unique cell, $\eta_T$, so that $\eta_T \subseteq \gamma$ for every $\gamma \in R_T$,

(E3) if $\eta_T$ is a $j$-cell then $\eta_T \cap bd V_T$ is a $(j-1)$-sphere, and

(E4) for each integer $k$ and each $k$-cell $\gamma \in R_T - \{ \eta_T \}$, $\gamma \cap bd V_T$ is a closed $(k-1)$-ball.

We call $\eta_T$ the hub of $R_T$. Furthermore, $S$ has the extended generic intersection property for $X$ if for every $T \subseteq S$ and every $\gamma \in R_T - R_T$ there is a $\delta \in R_T$ so that $\gamma \subseteq \delta$.

It is not difficult to see that if $X$ is a compact manifold and $S$ has the generic intersection and the closed ball properties for $X$, then the extended generic intersection and the extended closed ball properties follow. Indeed, the regular CW complex, $R$, required by condition (E1) consists of all non-empty sets $\bigcap V_T,X$ and $\bigcup V_T,bd X$, $T \subseteq S$. Fix a subset $T \subseteq S$ and define $F = \bigcap V_T,X$ and $G = \bigcap V_T,bd X$. If non-empty, $F$ and $G$ are closed balls, and if $G \neq \emptyset$ then $F \neq \emptyset$ and the dimension of
$F$ exceeds the dimension of $G$ by one. There are three possible cases. If $F = G = \emptyset$ then $\bigcap \mathcal{V}_T \times X = F = \emptyset$ and conditions (E2) through (E4) are void. If $F \neq \emptyset$ and $G = \emptyset$ then $\mathcal{R}_T^2 = \{F\}$, and $\eta_T = F$ satisfies conditions (E2) and (E3); condition (E4) is void. If $F \neq \emptyset$ and $G \neq \emptyset$ then $\mathcal{R}_T^2 = \{F, G\}$, $\eta_T = G$ satisfies conditions (E2) and (E3), and $\gamma = F$ satisfies condition (E4). In any case, the establishment of the homeomorphism in the proof of theorem 4.3 can be viewed as introducing a vertex $v_T$ for $\eta_T$ and connecting it to the simplices inductively constructed for the cells in $\mathcal{R}_T - \mathcal{R}_T^2$. This idea also works in the general case.

Let $X \subseteq \mathbb{R}^d$ be a topological space, and let $S \subseteq \mathbb{R}^d$ be a non-degenerate finite point set that has the extended generic intersection and the extended closed ball properties for $X$. To construct a homeomorphism between $X = \bigcup \mathcal{R}$ and $\bigcup \mathcal{D}_X$, we consider one subset $T \subseteq S$ at a time, in order of non-increasing cardinality. Inductively, we assume the cells in $\mathcal{R}_T - \mathcal{R}_T^2$ are already mapped homeomorphically to appropriate simplices. We extend the homeomorphism to the cells of $\mathcal{R}_T^2$, again inductively in order of non-decreasing dimension. We introduce a vertex, $v_T$, for the hub, $\eta_T$. If $\eta_T$ is a $k$-ball, its boundary is a $(k - 1)$-sphere, and by (E3) and the induction hypothesis, the cells in this $(k - 1)$-sphere are already part of the homeomorphism. After connecting $v_T$ to the simplices that correspond to the cells in $b \eta_T$, we can extend the homeomorphism to $\eta_T$. Every other cell in $\mathcal{R}_T^2$ is treated the same way, only that the reason the homeomorphism can be extended is now a combination of the two induction hypotheses. This implies the generalization of theorem 4.3 to topological spaces other than manifolds.

**THEOREM 5.1** Let $X \subseteq \mathbb{R}^d$ be a topological space, and let $S$ be a non-degenerate finite point set that has the extended generic intersection property for $X$. If $S$ has the extended closed ball property for $X$ then $\bigcup \mathcal{D}_X \approx X$.

6 Remarks and Further Work

This paper is targeted at problems requiring the discretization of possibly complicated geometric objects in finite-dimensional Euclidean spaces. Such problems are abundant in the computational science literature, see e.g. Kaufmann and Smarr [12], where the discretization of continuous domains is common practice. The dimensions of the domain and the imbedding space can be the same, as e.g. common in fluid dynamics problems, or they can be widely different, as in the study of many dynamical systems. The restricted Delaunay simplicial complex introduced in this paper is a general method that produces simplicial discretizations in all cases.

The introduction of a general concept typically gives rise to many specific questions and directions for further research. We see three directions of progressively more basic work necessary to bring restricted Delaunay simplicial complexes closer to the targeted application areas. The first is the design of efficient algorithms that constructs the Delaunay simplicial complex of a finite point set, $S$, restricted by a domain or space, $X$. Special cases under different assumptions on how $X$ is specified are considered in [15, 4, 8]. The second direction is the design of methods that choose finitely many points resulting in good quality discretizations of $X$. Such methods have a long history in the somewhat different context of finite element analysis, see e.g. [21]. The third direction is the study of maps from a problem specific domain to a space, possibly imbedded in higher dimensions, that depends on functionals studied over the domain or on approximate solutions thereof.
