Machine-Level Programming IV: Data

15-213/18-213/15-513: Introduction to Computer Systems
8th Lecture, September 21, 2017

Today’s Instructor:
Phil Gibbons
Today

- Arrays
  - One-dimensional
  - Multi-dimensional (nested)
  - Multi-level

- Structures
  - Allocation
  - Access
  - Alignment

- Floating Point
Array Allocation

- **Basic Principle**

  \[ T \ A[L]; \]

  - Array of data type \( T \) and length \( L \)
  - Contiguously allocated region of \( L \times \text{sizeof}(T) \) bytes in memory

```
char string[12];
```

```
int val[5];
```

```
double a[3];
```

```
char *p[3];
```
Array Access

■ Basic Principle

\[ T \ A[L]; \]

- Array of data type \( T \) and length \( L \)
- Identifier \( A \) can be used as a pointer to array element 0: Type \( T^* \)

\[
\begin{array}{c|c|c|c|c|c|c|c}
& 1 & 5 & 2 & 1 & 3 \\
\hline
x & x + 4 & x + 8 & x + 12 & x + 16 & x + 20 \\
\end{array}
\]

■ Reference | Type | Value
---|---|---
\( \text{val}[4] \) | int | 3
\( \text{val} \) | int * | 
\( \text{val} + 1 \) | int * | 
\( &\text{val}[2] \) | int * | 
\( \text{val}[5] \) | int | 
\( *(\text{val} + 1) \) | int | 
\( \text{val} + i \) | int * | 
Array Access

■ Basic Principle

\[ T \ A[L] ; \]

- Array of data type \( T \) and length \( L \)
- Identifier \( A \) can be used as a pointer to array element 0: Type \( T^* \)

\[
\begin{array}{c|c|c|c|c|c|c}
\hline
\text{int val[5];} & 1 & 5 & 2 & 1 & 3 \\
\text{x} & x + 4 & x + 8 & x + 12 & x + 16 & x + 20 \\
\hline
\end{array}
\]

■ Reference | Type | Value
---|---|---
val[4] | int | 3
val | int * | x
val+1 | int * | x + 4
&val[2] | int * | x + 8
val[5] | int | ??
*(val+1) | int | 5 //val[1]
val + i | int * | x + 4 * i //&val[i]
Array Example

```
#define ZLEN 5
typedef int zip_dig[ZLEN];

zip_dig cmu = { 1, 5, 2, 1, 3 };  
zip_dig mit = { 0, 2, 1, 3, 9 };  
zip_dig ucb = { 9, 4, 7, 2, 0 };  
```

- Declaration “zip_dig cmu” equivalent to “int cmu[5]”
- Example arrays were allocated in successive 20 byte blocks
  - Not guaranteed to happen in general
Array Accessing Example

```
int get_digit
    (zip_dig z, int digit)
{
    return z[digit];
}
```

### x86-64

- Register `%rdi` contains starting address of array
- Register `%rsi` contains array index
- Desired digit at `%rdi + 4*%rsi`
- Use memory reference `%rdi, %rsi, 4`

```
#  %rdi = z
#  %rsi = digit
movl (%rdi,%rsi,4), %eax  #  z[digit]
```
Array Loop Example

```c
void zincr(zip_dig z) {
    size_t i;
    for (i = 0; i < ZLEN; i++)
        z[i]++;
}
```

```assembly
# %rdi = z
    movl $0, %eax
    jmp .L3
.L4:
    addl $1, (%rdi,%rax,4)
    addq $1, %rax
.L3:
    cmpq $4, %rax
    jbe .L4
    rep; ret
```
# Understanding Pointers & Arrays #1

<table>

- **A3**
  - Gray block
  - Allocated int
  - Unallocated int
Multidimensional (Nested) Arrays

- **Declaration**
  
  \[ T \ A[R][C]; \]
  
  - 2D array of data type \( T \)
  - \( R \) rows, \( C \) columns

- **Array Size**
  
  - \( R \times C \times \text{sizeof}(T) \) bytes

- **Arrangement**
  
  - Row-Major Ordering

**Declaration**

\[
\text{int } A[R][C];
\]

**Arrangement**

- \( A[0][0] \) \( \cdots \) \( A[0][C-1] \)
- \( \vdots \)
- \( A[R-1][0] \) \( \cdots \) \( A[R-1][C-1] \)

**Diagram**

- 4\( R \times C \) Bytes

Nested Array Example

```c
#define PCOUNT 4
typedef int zip_dig[5];

zip_dig pgh[PCOUNT] =
    {{1, 5, 2, 0, 6},
     {1, 5, 2, 1, 3 },
     {1, 5, 2, 1, 7 },
     {1, 5, 2, 2, 1 }};
```

- “zip_dig pgh[4]” equivalent to “int pgh[4][5]”
  - Variable `pgh`: array of 4 elements, allocated contiguously
  - Each element is an array of 5 `int`’s, allocated contiguously

- “Row-Major” ordering of all elements in memory
Nested Array Row Access

- **Row Vectors**
  - \( A[i] \) is array of \( C \) elements of type \( T \)
  - Starting address \( A + i \times (C \times \text{sizeof}(T)) \)

```c
int A[R][C];
```

![Diagram](image-url)
Nested Array Row Access Code

- **Row Vector**
  - `pgh[index]` is array of 5 int’s
  - Starting address `pgh + 20 * index`

- **Machine Code**
  - Computes and returns address
  - Compute as `pgh + 4*(index + 4*index)`

```
int *get_pgh_zip(int index)
{
  return pgh[index];
}
```

```c
# %rdi = index
leaq (%rdi,%rdi,4),%rax # 5 * index
leaq pgh(,%rax,4),%rax # pgh + (20 * index)
```
Nested Array Element Access

- **Array Elements**
  - \( A[i][j] \) is element of type \( T \), which requires \( K \) bytes
  - Address \( A + i \times (C \times K) + j \times K \)
    \[
    = A + (i \times C + j) \times K
    \]

```c
int A[R][C];
```

```c
A+(i*C*4)
```

```c
A+(i*C*4)+(j*4)
```

```c
A+( (R-1)*C*4 )
```
 Nested Array Element Access Code

**Array Elements**

- \( pgh[\text{index}][\text{dig}] \) is int
- Address: \( pgh + 20*\text{index} + 4*\text{dig} \)
  
  \[= pgh + 4*(5*\text{index} + \text{dig})\]

```c
int get_pgh_digit(int index, int dig) {
    return pgh[index][dig];
}
```

```assembly
leaq (%rdi,%rdi,4), %rax  # 5*index
addl %rax, %rsi           # 5*index+dig
movl pgh(,%rsi,4), %eax  # M[pgh + 4*(5*index+dig)]
```
Multi-Level Array Example

- Variable `univ` denotes an array of 3 elements.
- Each element is a pointer:
  - 8 bytes
- Each pointer points to an array of `int`s.

```c
zipDig cmu = { 1, 5, 2, 1, 3 };
zipDig mit = { 0, 2, 1, 3, 9 };
zipDig ucb = { 9, 4, 7, 2, 0 };

#define UCOUNT 3
int *univ[UCOUNT] = {mit, cmu, ucb};
```
Element Access in Multi-Level Array

```c
int get_univ_digit(size_t index, size_t digit)
{
    return univ[index][digit];
}
```

Computation
- Element access $\text{Mem}[	ext{Mem}[\text{univ}+8*\text{index}]+4*\text{digit}]$
- Must do two memory reads
  - First get pointer to row array
  - Then access element within array

```
salq $2, %rsi           # 4*digit
addq univ(,%rdi,8), %rsi # p = univ[index] + 4*digit
movl (%rsi), %eax      # return *p
ret
```
Array Element Accesses

Nested array

```c
int get_pgh_digit(size_t index, size_t digit)
{
    return pgh[index][digit];
}
```

Multi-level array

```c
int get_univ_digit(size_t index, size_t digit)
{
    return univ[index][digit];
}
```

Accesses looks similar in C, but address computations very different:

\[
\text{Mem}[\text{pgh}+20\times\text{index}+4\times\text{digit}] \quad \text{Mem}[\text{Mem}[\text{univ}+8\times\text{index}]+4\times\text{digit}]
\]
### N × N Matrix

#### Code

- **Fixed dimensions**
  - Know value of $N$ at compile time

- **Variable dimensions, explicit indexing**
  - Traditional way to implement dynamic arrays

- **Variable dimensions, implicit indexing**
  - Now supported by gcc

```c
#define N 16
typedef int fix_matrix[N][N];
/* Get element $A[i][j]$ */
int fix_ele(fix_matrix A,
            size_t i, size_t j)
{
    return A[i][j];
}

#define IDX(n, i, j) ((i)*(n)+(j))
/* Get element $A[i][j]$ */
int vec_ele(size_t n, int *A,
            size_t i, size_t j)
{
    return A[IDX(n,i,j)];
}

/* Get element $a[i][j]$ */
int var_ele(size_t n, int A[n][n],
            size_t i, size_t j) {
    return A[i][j];
}
```
16 X 16 Matrix Access

Array Elements

- `int A[16][16];`
- Address `A + i * (C * K) + j * K`
- `C = 16, K = 4`

```c
/* Get element A[i][j] */
int fix_ele(fix_matrix A, size_t i, size_t j) {
    return A[i][j];
}
```

```assembly
# A in %rdi, i in %rsi, j in %rdx
salq $6, %rsi    # 64*i
addq %rsi, %rdi  # A + 64*i
movl (%rdi,%rdx,4), %eax # M[A + 64*i + 4*j]
ret
```
**n X n Matrix Access**

- **Array Elements**
  - `size_t n;`
  - `int A[n][n];`
  - Address `A + i * (C * K) + j * K`
  - `C = n, K = 4`
  - Must perform integer multiplication

```c
/* Get element A[i][j] */
int var_ele(size_t n, int A[n][n], size_t i, size_t j)
{
    return A[i][j];
}
```

```assembly
# n in %rdi, A in %rsi, i in %rdx, j in %rcx
imulq %rdx, %rdi      # n*i
leaq (%rsi,%rdi,4), %rax # A + 4*n*i
movl (%rax,%rcx,4), %eax # A + 4*n*i + 4*j
ret
```
Example: Array Access

```c
#include <stdio.h>
#define ZLEN 5
#define PCOUNT 4
typedef int zip_dig[ZLEN];

int main(int argc, char** argv) {
    zip_dig pgh[PCOUNT] =
    {{1, 5, 2, 0, 6},
     {1, 5, 2, 1, 3 },
     {1, 5, 2, 1, 7 },
     {1, 5, 2, 2, 1 }};
    int *linear_zip = (int *) pgh;
    int *zip2 = (int *) pgh[2];
    int result =
        pgh[0][0] +
        linear_zip[7] +
        *(linear_zip + 8) +
        zip2[1];
    printf("result: %d\n", result);
    return 0;
}
```

```
linux> ./array
result: 9
```
Example: Array Access

```c
#include <stdio.h>
#define ZLEN 5
#define PCOUNT 4
typedef int zip_dig[ZLEN];

int main(int argc, char** argv) {
    zip_dig pgh[PCOUNT] =
    {{1, 5, 2, 0, 6},
     {1, 5, 2, 1, 3 },
     {1, 5, 2, 1, 7 },
     {1, 5, 2, 2, 1 }};
    int *linear_zip = (int *) pgh;
    int *zip2 = (int *) pgh[2];
    int result =
        pgh[0][0] +
        linear_zip[7] +
        *(linear_zip + 8) +
        zip2[1];
    printf("result: %d\n", result);
    return 0;
}
```

```bash
linux> ./array
result: 9
```
Quiz Time!

Check out:

https://canvas.cmu.edu/courses/1221
Today

- **Arrays**
  - One-dimensional
  - Multi-dimensional (nested)
  - Multi-level

- **Structures**
  - Allocation
  - Access
  - Alignment

- **Floating Point**
Structure Representation

- Structure represented as block of memory
  - Big enough to hold all of the fields
- Fields ordered according to declaration
  - Even if another ordering could yield a more compact representation
- Compiler determines overall size + positions of fields
  - Machine-level program has no understanding of the structures in the source code

```
struct rec {
    int a[4];
    size_t i;
    struct rec *next;
};
```
Generating Pointer to Structure Member

```c
struct rec {
    int a[4];
    size_t i;
    struct rec *next;
};
```

### Generating Pointer to Array Element
- Offset of each structure member determined at compile time
- Compute as \( r + 4 \times \text{idx} \)

```c
int *get_ap
(struct rec *r, size_t idx)
{
    return &r->a[idx];
}
```

```assembly
# r in %rdi, idx in %rsi
leaq (%rdi,%rsi,4), %rax
ret
```
Following Linked List

C Code

```c
void set_val (struct rec *r, int val)
{
    while (r) {
        int i = r->i;
        r->a[i] = val;
        r = r->next;
    }
}
```

```
.L11:
    movslq 16(%rdi), %rax # i = M[r+16]
    movl %esi, (%rdi,%rax,4) # M[r+4*i] = val
    movq 24(%rdi), %rdi # r = M[r+24]
    testq %rdi, %rdi # Test r
    jne .L11 # if !=0 goto loop
```

Structure: 0: a 16i 24next
Structures & Alignment

- **Unaligned Data**
  - Primitive data type requires $K$ bytes
  - Address must be multiple of $K$

- **Aligned Data**
  - Primitive data type requires $K$ bytes
  - Address must be multiple of $K$

```c
struct S1 {
    char c;
    int i[2];
    double v;
} *p;
```
Alignment Principles

- **Aligned Data**
  - Primitive data type requires \( K \) bytes
  - Address must be multiple of \( K \)
  - Required on some machines; advised on x86-64

- **Motivation for Aligning Data**
  - Memory accessed by (aligned) chunks of 4 or 8 bytes (system dependent)
    - Inefficient to load or store datum that spans cache lines (64 bytes). Intel states should avoid crossing 16 byte boundaries.
    - Virtual memory trickier when datum spans 2 pages (4 KB pages)

- **Compiler**
  - Inserts gaps in structure to ensure correct alignment of fields
Specific Cases of Alignment (x86-64)

- **1 byte: char, ...**
  - no restrictions on address

- **2 bytes: short, ...**
  - lowest 1 bit of address must be $0_2$

- **4 bytes: int, float, ...**
  - lowest 2 bits of address must be $00_2$

- **8 bytes: double, long, char *, ...**
  - lowest 3 bits of address must be $000_2$
Satisfying Alignment with Structures

- **Within structure:**
  - Must satisfy each element’s alignment requirement

- **Overall structure placement**
  - Each structure has alignment requirement $K$
    - $K = \text{Largest alignment of any element}$
  - Initial address & structure length must be multiples of $K$

- **Example:**
  - $K = 8$, due to `double` element

```
struct S1 {
    char c;
    int i[2];
    double v;
} *p;
```
Meeting Overall Alignment Requirement

- For largest alignment requirement $K$
- Overall structure must be multiple of $K$

```c
struct S2 {
    double v;
    int i[2];
    char c;
} *p;
```
Arrays of Structures

- Overall structure length multiple of K
- Satisfy alignment requirement for every element

```c
struct S2 {
    double v;
    int i[2];
    char c;
} a[10];
```
Accessing Array Elements

- Compute array offset 12*idx
  - `sizeof(S3)`, including alignment spacers
- Element j is at offset 8 within structure
- Assembler gives offset a+8
  - Resolved during linking

```c
short get_j(int idx)
{
    return a[idx].j;
}
```

```c
#define a+0          a[0]
#define a+12         a[12]
#define a+12*idx     a[12*idx]
#define a+12*idx+8   a[12*idx+8]
```

```asm
# %rdi = idx
leaq (%rdi,%rdi,2),%rax  # 3*idx
movzwl  a+8(%rax,4),%eax
```

```c
struct S3 {
    short i;
    float v;
    short j;
} a[10];
```
Saving Space

- Put large data types first

```c
struct S4 {
    char c;
    int i;
    char d;
} *p;
```

```c
struct S5 {
    int i;
    char c;
    char d;
} *p;
```

- Effect (largest alignment requirement K=4)
Example Struct Exam Question

Problem 5. (8 points):
Struct alignment. Consider the following C struct declaration:

typedef struct {
    char a;
    long b;
    float c;
    char d[3];
    int *e;
    short *f;
} foo;

1. Show how foo would be allocated in memory on an x86-64 Linux system. Label the bytes with the names of the various fields and clearly mark the end of the struct. Use an X to denote space that is allocated in the struct as padding.

Example Struct Exam Question

Problem 5. (8 points):
Struct alignment. Consider the following C struct declaration:

typedef struct {
    char a;
    long b;
    float c;
    char d[3];
    int *e;
    short *f;
} foo;

1. Show how foo would be allocated in memory on an x86-64 Linux system. Label the bytes with the names of the various fields and clearly mark the end of the struct. Use an X to denote space that is allocated in the struct as padding.

Example Struct Exam Question (Cont’d)

Problem 5. (8 points):
Struct alignment. Consider the following C struct declaration:

typedef struct {
    char a;
    long b;
    float c;
    char d[3];
    int *e;
    short *f;
} foo;

2. Rearrange the elements of foo to conserve the most space in memory. Label the bytes with the names of the various fields and clearly mark the end of the struct. Use an X to denote space that is allocated in the struct as padding.

Example Struct Exam Question (Cont’d)

Problem 5. (8 points):

Struct alignment. Consider the following C struct declaration:

```c
typedef struct {
    char a;
    long b;
    float c;
    char d[3];
    int *e;
    short *f;
} foo;
```

2. Rearrange the elements of `foo` to conserve the most space in memory. Label the bytes with the names of the various fields and clearly mark the end of the struct. Use an X to denote space that is allocated in the struct as padding.

---

Today

- **Arrays**
  - One-dimensional
  - Multi-dimensional (nested)
  - Multi-level

- **Structures**
  - Allocation
  - Access
  - Alignment

- **Floating Point**
Background

- **History**
  - x87 FP
    - Legacy, very ugly
  - SSE FP
    - Supported by Shark machines
    - Special case use of vector instructions
  - AVX FP
    - Newest version
    - Similar to SSE (but registers are 32 bytes instead of 16)
    - Documented in book
## Programming with SSE3

**XMM Registers**

- **16 total, each 16 bytes**
- **16 single-byte integers**

- **8 16-bit integers**

- **4 32-bit integers**

- **4 single-precision floats**

- **2 double-precision floats**

- **1 single-precision float**

- **1 double-precision float**
Scalar & SIMD Operations

- Scalar Operations: Single Precision
  - `addss %xmm0, %xmm1`
  - `%xmm0`
  - `%xmm1`

- SIMD Operations: Single Precision
  - `addps %xmm0, %xmm1`
  - `%xmm0`
  - `%xmm1`

- Scalar Operations: Double Precision
  - `addsd %xmm0, %xmm1`
  - `%xmm0`
  - `%xmm1`
**FP Basics**

- Arguments passed in %xmm0, %xmm1, ...
- Result returned in %xmm0
- All XMM registers caller-saved

```c
float fadd(float x, float y)
{
    return x + y;
}

double dadd(double x, double y)
{
    return x + y;
}
```

```assembly
# x in %xmm0, y in %xmm1
addss   %xmm1, %xmm0
ret

# x in %xmm0, y in %xmm1
addsd  %xmm1, %xmm0
ret
```
FP Memory Referencing

- Integer (and pointer) arguments passed in regular registers
- FP values passed in XMM registers
- Different mov instructions to move between XMM registers, and between memory and XMM registers

```c
double dincr(double *p, double v)
{
    double x = *p;
    *p = x + v;
    return x;
}
```

```assembly
# p in %rdi, v in %xmm0
movapd %xmm0, %xmm1   # Copy v
movsd (%rdi), %xmm0    # x = *p
addsd %xmm0, %xmm1    # t = x + v
movsd %xmm1, (%rdi)    # *p = t
ret
```
Other Aspects of FP Code

- *Lots of instructions*
  - Different operations, different formats, ...

- **Floating-point comparisons**
  - Instructions `ucomiss` and `ucomisd`
  - Set condition codes CF, ZF, and PF

- **Using constant values**
  - Set XMM0 register to 0 with instruction `xorpd %xmm0, %xmm0`
  - Others loaded from memory
Summary

- **Arrays**
  - Elements packed into contiguous region of memory
  - Use index arithmetic to locate individual elements

- **Structures**
  - Elements packed into single region of memory
  - Access using offsets determined by compiler
  - Possible require internal and external padding to ensure alignment

- **Combinations**
  - Can nest structure and array code arbitrarily

- **Floating Point**
  - Data held and operated on in XMM registers
## Understanding Pointers & Arrays #3
