"System call abuse for fun & profit"

The Thread
Jan. 26, 2004

Dave Eckhardt

Bruce Maggs

Synchronization

Budget your time for Project 1

- Start getting used to simics *right away*

This isn't like other programming

- C (not C++, not Java) – things don't happen for you
- Assembly language
- Hardware isn't clean

Write good code

- Console driver will be used *(and extended)* in P3

Road Map

Thread lecture

Synchronization lectures

- Probably *three*

Yield lecture

This is important

- When you leave here, you will use threads
- Understanding threads will help you understand the kernel

Please make sure you *understand* threads

- We'll try to help by assigning you P2

Outline

Textbook chapters

- Already: Chapters 1 through 4
- Today: Chapter 5 (roughly)
- Soon: Chapters 7 & 8
- Transactions (7.9) will be deferred

Outline

Thread = schedulable registers

- (that's *all* there is)

Why threads?

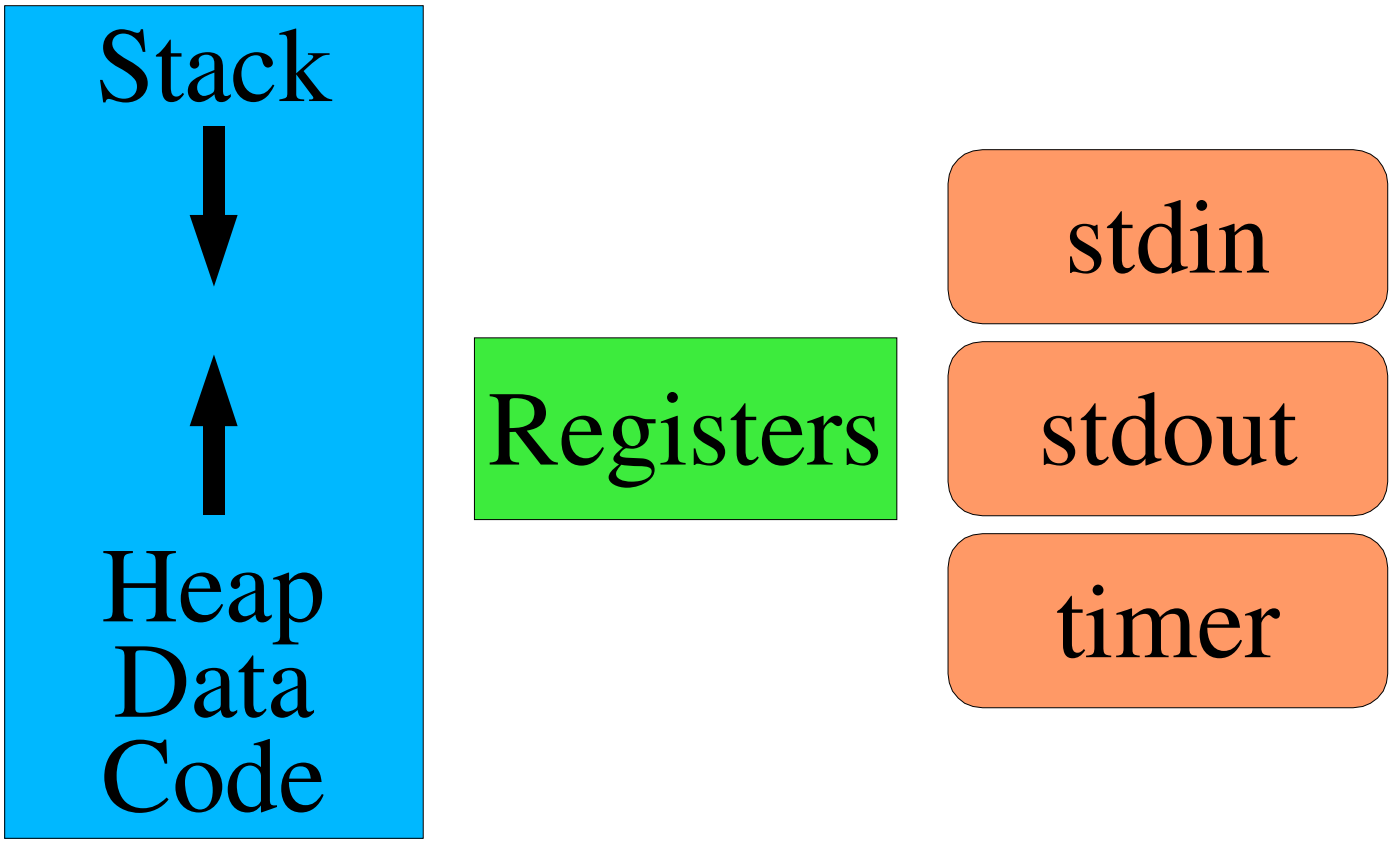
Thread flavors (ratios)

(Against) cancellation

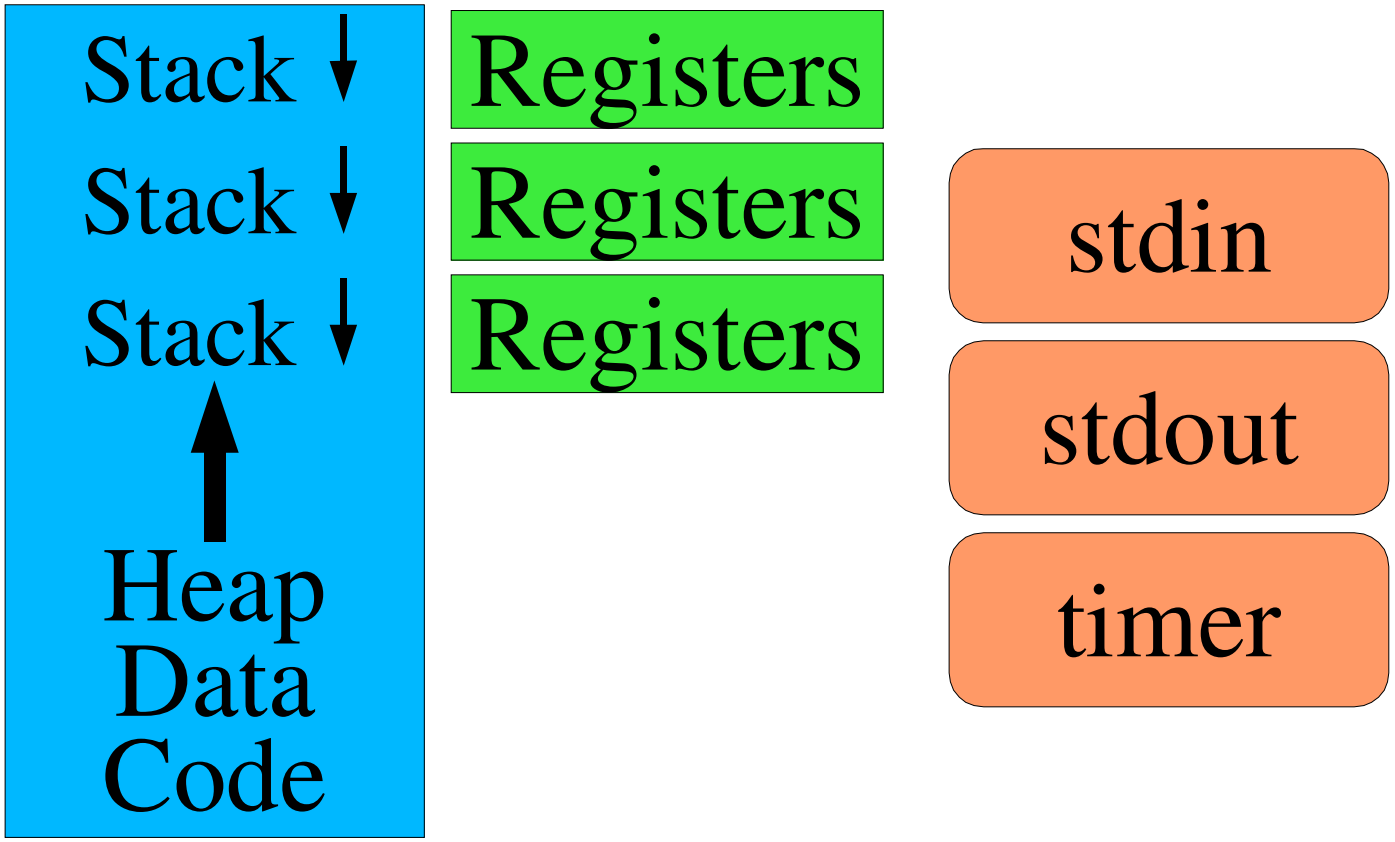
Race conditions

- 1 simple, 1 ouch
- *Make sure you really understand this*

Single-threaded Process



Multi-threaded Process



What does that *mean*?

Three stacks

- Three sets of “local variables”

Three register sets

- Three stack pointers
- Three %eax's (etc.)

Three *schedulable RAM mutators*

- (heartfelt but partial apologies to the ML crowd)

Three potential bad interactions

Why threads?

Shared access to data structures

Responsiveness

Speedup on multiprocessors

Shared access to data structures

Database server for multiple bank branches

- Verify multiple rules are followed
  - Account balance
  - Daily withdrawal limit
- Multi-account operations (transfer)
- Many accesses, each modifies tiny fraction of database

Server for a multi-player game

- Many players
- Access (& update) shared world state
  - Scan multiple objects
  - Update one or two objects

Shared access to data structures

Process per player?

- *Processes* share objects only via system calls
- Hard to make game objects = operating system objects

Process per game object?

- "Scan multiple objects, update one"
- Lots of message passing between processes
- Lots of memory wasted for lots of processes
- *Slow*

Shared access to data structures

Thread **per player**

- Game objects inside single memory address space
- Each thread can access & update game objects
- Shared access to OS objects (files)

Thread-switch is cheap

- Store N registers
- Load N registers

Responsiveness

"Cancel" button vs. decompressing large JPEG

- Handle mouse click *during* 10-second process
  - Map (x,y) to "cancel button" area
  - Verify that button-release happens in button area of screen
- ...without JPEG decompressor understanding clicks

Multiprocessor speedup

More CPUs can't help a single-threaded process!

PhotoShop color dither operation

- Divide image into regions
- One dither thread per CPU
- Can (sometimes) get linear speedup

Kinds of threads

User-space (N:1)

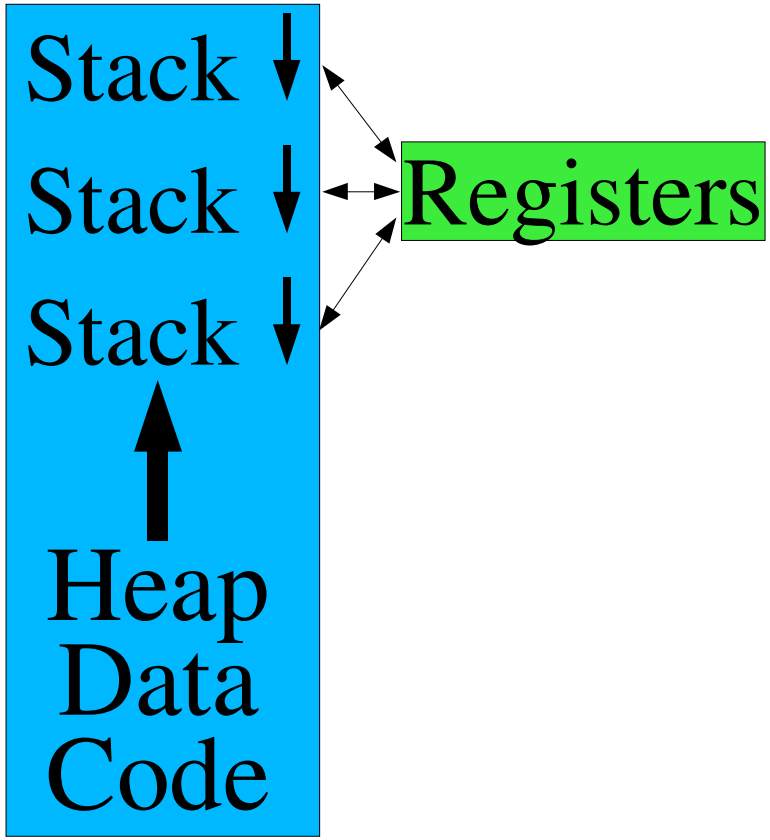
Kernel threads (1:1)

Many-to-many (M:N)

User-space threads (N:1)

Internal threading

- Thread library adds threads to a process
- Thread switch just swaps registers



User-space threads (N:1)

No change to operating system

System call probably blocks all "threads"

- Kernel blocks "the process"
- (special non-blocking system calls can help)

"Cooperative scheduling" awkward/insufficient

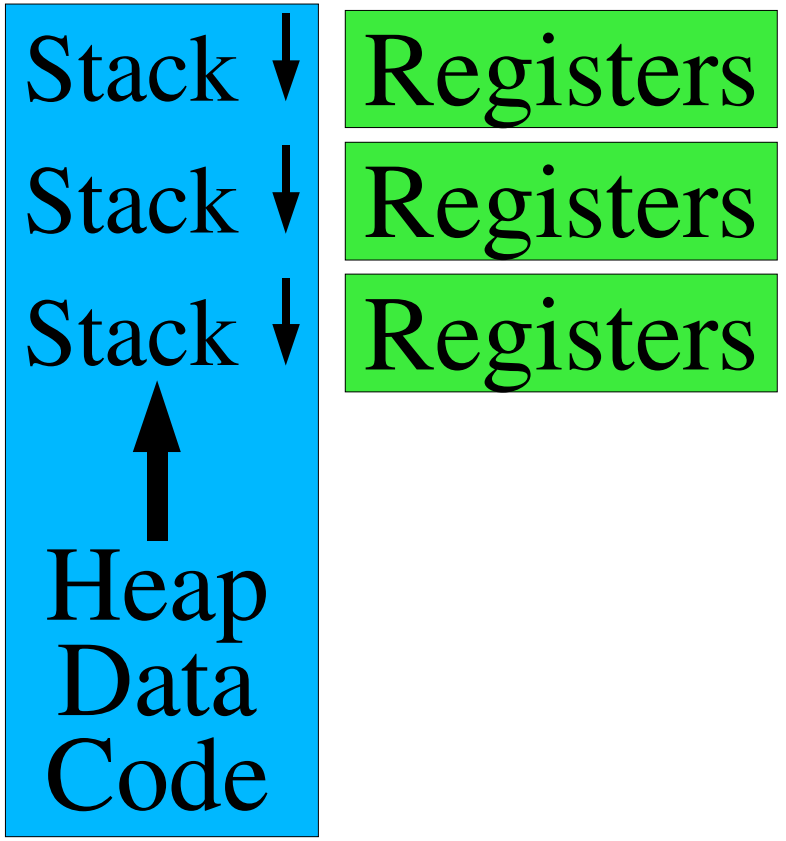
- Must manually insert many calls to yield()

Cannot go faster on multiprocessor machines

Pure kernel threads (1:1)

OS-supported threading

- OS knows thread/process ownership
- Memory regions shared & reference-counted



Pure kernel threads (1:1)

Every thread is sacred

- Kernel-managed register set
- Kernel stack
- “Real” (timer-triggered) scheduling

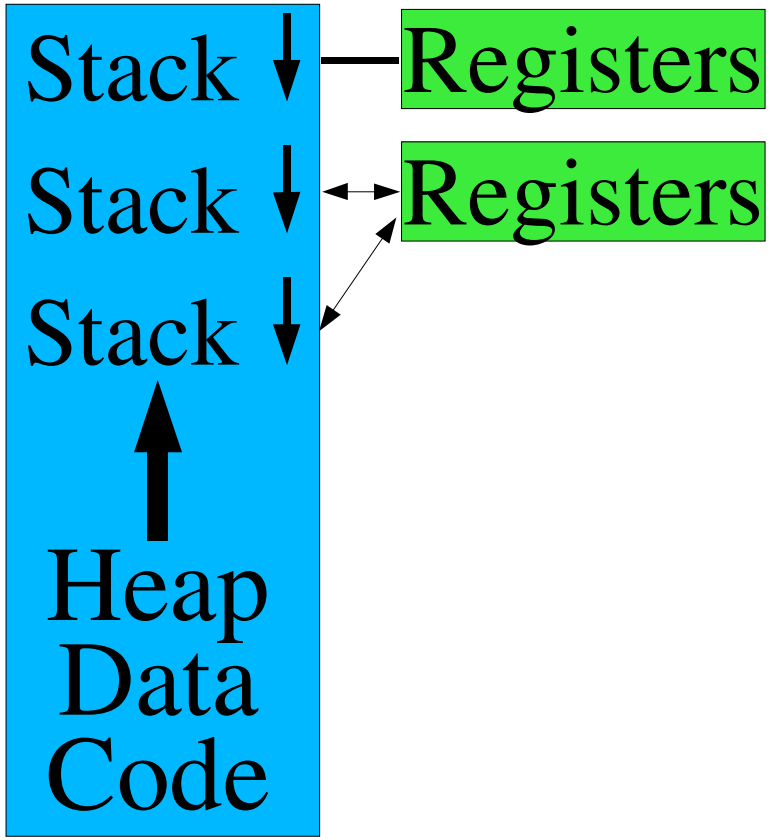
Features

- Program runs faster on multiprocessor
- User-space libraries must be rewritten
- Require kernel memory (PCB, stack)

Many-to-many (M:N)

Middle ground

- OS provides kernel threads
- M user threads share N kernel threads



Many-to-many (M:N)

Sharing patterns

- Dedicated
  - User thread 12 owns kernel thread 1
- Shared
  - 1 kernel thread per hardware CPU
  - Kernel thread executes next runnable user thread
- Many variations, see text

Features

- Great when scheduling works as you expected!

(Against) Thread Cancellation

Thread cancellation

- We don't want the result of that computation
  - ("Cancel button")

Asynchronous (immediate) cancellation

- Stop execution *now*
  - Free stack, registers
  - Poof!
- Hard to garbage-collect resources (open files, ...)
- Invalidates data structure consistency!

(Against) Thread Cancellation

Deferred ("pretty please") cancellation

- Write down “thread #314, please go away”
- Threads must check for cancellation
- Or define safe cancellation points
  - “Any time I call close() it's ok to zap me”

The only safe way (IMHO)

Race conditions

What you think

```
ticket = next_ticket++; /* 0 ⇒ 1 */
```

What really happens (in general)

```
ticket = temp = next_ticket; /* 0 */
++temp; /* 1, but not visible */
next_ticket = temp; /* 1 is visible */
```

Murphy' s Law (of threading)

The world may *arbitrarily interleave* execution

It will choose the *most painful* way

- **"Once chance in a million" happens every minute**

What you hope for

T0		*T1*	
`tkt = tmp = n_tkt;`	0		
`++tmp;`	1		
`n_tkt = tmp;`	1		
		`tkt = tmp = n_tkt;`	1
		`++tmp;`	2
		`n_tkt = tmp;`	2

Race Condition Example

T0		*T1*	
`tkt = tmp = n_tkt;`	0		
		`tkt = tmp = n_tkt;`	0
`++tmp;`	1		
		`++tmp;`	1
`n_tkt = tmp;`	1		
		`n_tkt = tmp;`	1

Two threads have same "ticket"!

What happened?

Each thread did "something reasonable"

- ...assuming no other thread were touching those objects
- ...assuming *"mutual exclusion"*

The world is cruel

- Any possible scheduling mix *will* happen

The #! shell-script hack

What's a "shell script"?

- A file with a bunch of (shell-specific) shell commands

```
#!/bin/sh
echo "My hovercraft is full of eels"
sleep 10
exit 0
```

The #! shell-script hack

What's "#!"?

- A venerable hack

You say

```
execl("/foo/script", "script", "arg1", 0);
```

/foo/script begins...

```
#!/bin/sh
```

The kernel does...

```
execl("/bin/sh" "/foo/script" "arg1" , 0);
```

The shell does

```
open("/foo/script", O_RDONLY, 0)
```

The setuid invention

U.S. Patent #4,135,240

- Dennis M. Ritchie
- January 16, 1979

The concept

- A program with *stored privileges*
- When executed, runs with *two* identities
  - invoker's identity
  - file owner's identity

Setuid example - printing a file

Goals

- Every user can queue files
- Users cannot delete other users' files

Solution

- Queue directory owned by user `printer`
- Setuid `queue-file` program
  - Create queue file as user `printer`
  - Copy joe's data as user `joe`
- User `printer` controls user `joe`'s queue access

Race condition example

Process 0	*Process 1*
`ln -s /bin/lpr /tmp/lpr`	
	`run /tmp/lpr`
	`[become printer]`
	`run /bin/sh /tmp/lpr`
`rm /tmp/lpr`	
`ln -s /my/exploit /tmp/lpr`	
	`script = open("/tmp/lpr");`
	`execute /my/exploit`

What happened?

Intention

- Assign privileges to program contents

What happened?

- Privileges were assigned to program *name*
- Program name pointed to different *contents*

How would you fix this?

How to solve race conditions?

Carefully analyze operation sequences

Find subsequences which must be *uninterrupted*

- **"Critical section"**

Use a *synchronization mechanism*

- **Next time!**

Summary

Thread: What, why

Thread flavors (ratios)

Race conditions

- *Make sure you really understand this*
