15-410 "...process_switch(P2) 'takes a while'..."

Yield Feb. 10, 2006

Dave Eckhardt
Bruce Maggs

- 1 - L12a_Yield 15-410, S'06

Road Map

Day	Option 1	Option 2
Friday	Yield	Yield
Monday	Deadlock	Deadlock
Wednesday	Deadlock	Deadlock
Friday	P2 questions	VM1
Monday	VM1	P2 questions
Wednesday	VM2	VM2

My suggestion: Option 1

Either will require *you* to come to class with questions! (I will come to class with a lecture..don't make me use it)

- 2 - 15-410, S'06

Outline

Context switch

- Motivated by yield()
- This is a *core idea* of this class
 - You will benefit if your P3 implementation is clean and solid
 - There's more than one way to do it
 - Even more than one good way
 - As with P2 thread_fork part of the design is figuring out what parameters context_switch should take...
- This lecture is "early"
 - Struggle with it today
 - Hopefully it'll be easier when you struggle with it in P3
- Note: today we'll talk about every kind of thread but P2

- 3 -

Mysterious yield()

```
T1() { T2() {
  while (1) while (1)
  yield(T2); yield(T1);
}
```

- 4 -

User-space Yield

Consider pure user-space threads

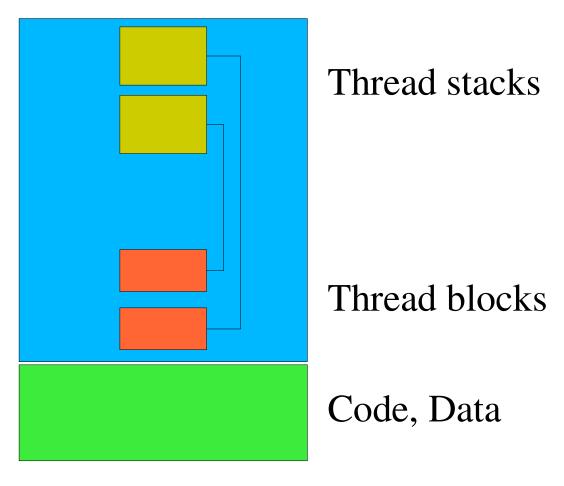

- The opposite of Project 2
- You implement threads inside a single-threaded process
- There is no thread_fork...

What is a thread in that world?

- A stack
- "Thread control block" (TCB)
 - Locator for register-save area
 - Housekeeping information

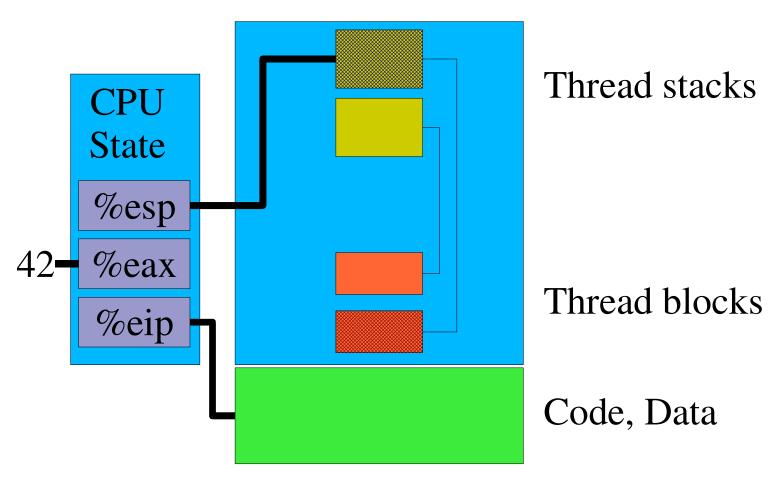

- 5 -

Big Picture

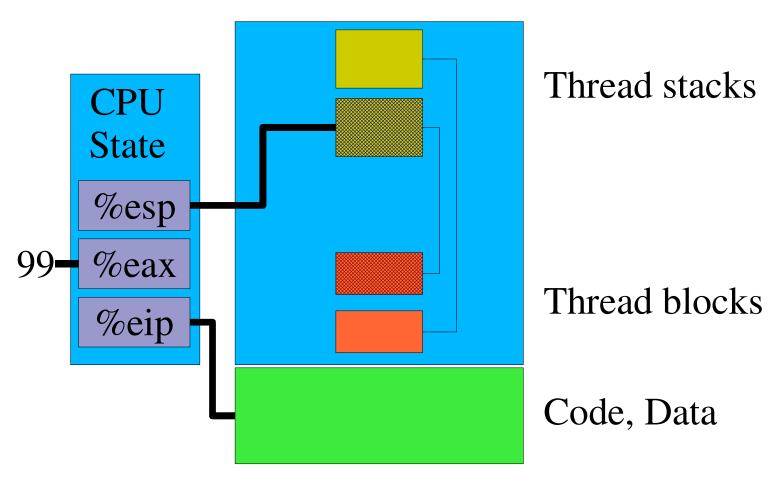

- 6 -

Big Picture

- 7 -

Running the Other Thread

- 8 -

User-space Yield

yield(user-thread-3)

save my registers on stack

/* magic happens here */

restore thread 3's registers from thread 3's stack

return; /* to thread 3! */

- 9 -

Todo List

General-purpose registers
Stack pointer
Program counter

- 10 -

No magic!

```
/* C, asm() may not be best for this! */
yield(user-thread-3) {
  save registers on stack /* asm(...) */
 tcb->sp = get_esp(); /* asm(...) */
 tcb->pc = &there; /* gcc ext. */
 tcb = findtcb(user-thread-3);
  set_esp(tcb->sp);
                           /* asm(...) */
                           /* asm(...) */
  jump (tcb->pc);
there:
  restore registers from stack /* asm() */
  return;
```

- 11 - 15-410, S'06

The Program Counter

What values can the PC (%eip) contain?

- In a pure user-thread environment, thread switch happens only in yield
- Yield sets saved PC to start of "restore registers"

All non-running threads have the same saved PC

Please make sure this makes sense to you

- 12 -

Remove Unnecessary Code – 1

```
yield(user-thread-3) {
  save registers on stack
  tcb->sp = get_esp();
  * ¢ b + * p c / ≠ / & t h e t e /
  tcb = findtcb(user-thread-3);
  set_esp(tcb->sp);
  jump (≠¢♭/≯ø¢ &there);
there:
  restore registers from stack
  return
```

- 13 -

Remove Unnecessary Code – 2

```
yield(user-thread-3) {
   save registers on stack
   tcb->sp = get_esp();
   tcb = findtcb(user-thread-3);
   set_esp(tcb->sp);
   restore registers from stack
   return
}
```

- 14 -

User Threads vs. Kernel Processes

What if a process yields to another?

- "Compare & contrast, in no more than 1,000 words..."

User threads

- Share memory
- Threads not protected from each other

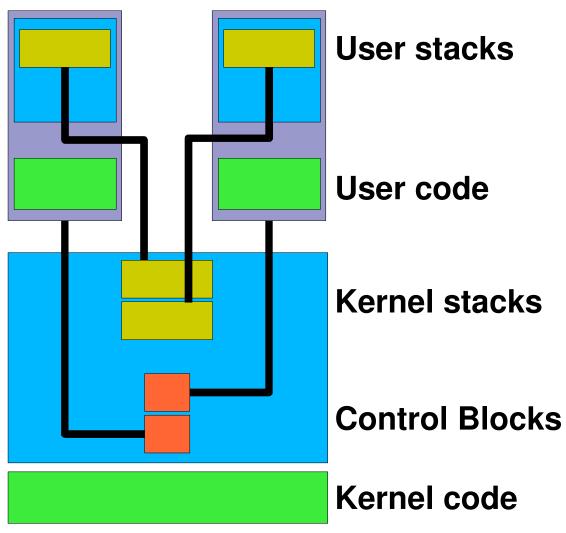

Processes

- Do not generally share memory
- P1 must not modify P2's saved registers

Where are process save areas and control blocks?

- 15 - 15-410, S'06

Kernel Memory Picture

- 16 -

P1's Yield(P2) steps

P1 calls yield(P2)

INT $50 \Rightarrow boom!$

Processor trap protocol

- Saves some registers on P1's kernel stack
 - This is a stack switch (user ⇒ kernel), intel-sys.pdf 5.10
 - Top-of-kernel-stack specified by %esp0 register
 - Trap frame (x86): %ss & %esp, %eflags, %cs & %eip

Assembly-language stub

- Saves more registers
- Starts C trap handler

P1's Yield(P2) steps

sys_yield()

- return(process_switch(P2))

Assembly-language stub

Restores registers from P1's kernel stack

Processor return-from-trap protocol (aka IRET)

- Restores %ss & %esp, %eflags, %cs & %eip

INT 50 instruction "completes"

Back in user-space

P1 yield() library routine returns

- 18 -

What happened to P2??

process_switch(P2) "takes a while"

- When P1 calls it, it "returns" to P2
- When P2 calls it, it "returns" to P1 (eventually)

- 19 -

Inside process_switch()

ATOMICALLY

- 20 - 15-410, S'06

User-mode Yield vs. Kernel-mode

Kernel context switches happen for more reasons

- good old yield(), but also...
- Message passing from P1 to P2
- P1 sleeping on disk I/O, so run P2
- CPU preemption by clock interrupt

- 21 - 15-410, S'06

I/O completion Example

P1 calls read()

In kernel

- read() starts disk read
- read() calls condition_wait(&buffer); /* details vary */
- condition_wait() calls process_switch()
- process_switch() returns to P2

- 22 - 15-410, S'06

I/O Completion Example

While P2 is running

- Disk completes read, interrupts P2 into kernel
- Interrupt handler calls condition_signal(&buffer);

Option 1

- condition_signal() marks P1 as runnable, returns
- Interrupt handler returns to P2

Option 2

- condition_signal() calls process_switch(P1) (only fair...)
- P2 will finish the interrupt handler much later
 - Remember in P3 to confront implications of this!

- 23 - 15-410, S'06

Clock interrupts

P1 doesn't "ask for" clock interrupt

- Clock handler forces P1 into kernel
 - Kernel stack looks like a "system call"
 - As if user process had called handle_timer()
 - But it was involuntary

P1 doesn't say who to yield to

- (it didn't make the "system call")
- Scheduler chooses next process

- 24 - 15-410, S'06

Summary

Similar steps for user space, kernel space

Primary differences

- Kernel has open-ended competitive scheduler
- Kernel more interrupt-driven

Implications for 410 projects

- P2: firmly understand thread stacks
 - thread_create() stack setup
 - cleanup
 - race conditions
- P3: firmly understand kernel context switch

Advice: draw pictures of stacks

- 25 - 15-410, S'06
