

**15-410**

***“Now that we've covered the 1970's...”***

**Plan 9**  
**Apr. 9, 2007**

**Dave Eckhardt**

**Bruce Maggs**

# Synchronization

## Survey

- How many have installed \*nix on a box?
  - Windows?
- How many have *done an in-place upgrade?*
- How many have a personally owned box with multiple users?
  - Done an upgrade?
- What does “PC” stand for?

## Today: Plan 9 from Bell Labs

# Overview

## What style of computing?

- The death of timesharing
- The “Unix workstation problem”

## Design principles

## Runtime environment

## File servers (TCP file system)

## Name spaces

# Timesharing

## One computer per ...

- City: Multics
- Campus: IBM mainframe
- Department: minicomputer

## Benefits

- Sharing, protection easy inside “the community”
  - Easy to add a “user” to access control list (or user group)
- Administration amortized across user base
  - Backups & printers, too...

# The *Personal Computing* Revolution

**Consequence of the microprocessor**

**Get *your own* machine!**

**No more “disk quota”**

***You* decide which software is on the box**

- Upgrade whenever *you* want
  - Mainframe sysadmin's schedule is *always* too (fast xor slow)

**Great!**

# The Rallying Cry

**One of the Alto's most attractive features is that it does not run faster at night.**

- Butler Lampson?

# The Personal Computing *Disaster*

## *You* do your own backups

- Probably not!

## *You* do emergency security upgrades

- Day or night!

## Sharing files is hard, risky

- machine:/usr/... (until it retires)

## Every machine you use has different software

- If you're lucky, packages are just missing
- If you're unlucky, they're there with subtly wrong versions
  - Or different machines have different fonts –whee!

# Hybrid Approach

## Distributed computing

- Centralize “the right” resources
  - Backed-up, easily-shared file systems
  - Complex (licensed) software packages
  - Version management / bug patches
- Access those resources from a fast local machine

## Which OS on the servers?

- Don't care –black boxes

## Which OS on the workstation?

# Workstation Operating Systems

## Unix?

- Good: It's the system you're used to using
- Bad: Administer it yourself
  - `/etc/passwd`, `/etc/group`, anti-relay your sendmail...

## Windows

- Your very own copy of VMS!
- Support for organization-wide user directory
- Firm central control over machine
  - “install software” is a privilege
- Access to *services* is tied to *machines*
- Firmly client/server (no distributed execution)

# Workstation Operating Systems

## Mac OS 9

- Your own ... whatever it was

## Mac OS X

- Your own Unix system! (see above)

## VM/CMS or MVS!!!

- IBM PC XT/370
- Your own *mainframe!*
  - You and your *whole family* can (must) administer it

# The “Network Computer”

**Your own display, keyboard, mouse**

**Log in to a real computer for your real computing**

**Every keystroke & every mouse click cross the net**

- Every font glyph...

**Also known as**

- Thin client, X terminal, Windows Terminal Services

**Once “The Next Big Thing”**

- (thud)

# The Core Issues

**Who defines and administers resources?**

**What travels across the network?**

- X terminal: keystrokes, bitmaps
- AFS: files

**Are legacy OS's right for this job?**

# The Plan 9 Approach

## **“Build a UNIX out of little systems”**

- ...not “a system out of little Unixes”

## **Compatibility of essence with Unix**

- Not real portability

## **Take the good things**

- Tree-structured file system
- “Everything is a file” model

## **Toss the rest (ttys, *signals!*)**

# Design Principles

## “Everything is a file”

- Standard *naming system* for all resources: pathnames

## “Remote access” is the common case

- Standard *resource access protocol*: “9P”
- Used to access any file-like thing, remote or local

## Personal namespaces

- Naming *conventions* keep it sane

## A practical issue: Open Source

- Unix source not available at “Bell Labs”, its birthplace!

# System Architecture

## Reliable machine-room *file servers*

- Plan 9's eternal versioned file system

## Shared-memory multiprocessor *cycle servers*

- Located near file servers for fast access

## Remote-access workstation *terminals*

- Access your *view* of the environment
- Don't *contain* your environment
- Disk is optional
  - Typically used for faster booting, file cache
- “Root directory” is located on your primary file server

/usr/rob/lib/plumbing Del Snarf | Look

[# to update: cp /usr/\$user/lib/plumbing /mnt/

plumb/rules

editor = acme

# Custom Namespaces

**/bin/date** means *your architecture's* binary

**/dev/cons** means *your* terminal

- Per-*window* devices (below)

**/mail/fs/mbox/25** is the 25<sup>th</sup> message in your box

**No “links” - “hard” or “soft”**

- A link is something *in the file system* which causes everybody to buy into a naming illusion
  - Some illusions cause security holes, as we've seen
- In Plan 9, namespaces are *consensual* illusions
  - Stored in process control blocks, not in the file system

# The /bin File System

**Look, Ma, no \$PATH!**

```
% bind /386/bin /bin
```

```
% bind -a /rc/bin /bin
```

```
% bind -a /usr/davide/386/bin /bin
```

**/bin is a *union* directory**

- Each backing directory searched in order

# /dev/tty vs. /dev/cons

```
% (process_foo <foo >bar ) >&errs
```

- csh-speak for
  - Run “process\_foo”
  - Standard input is “foo”
  - Standard output sent to “bar”
  - Standard error sent to “errs”

“process\_foo” is pretty well connected to *files*

- What if it wants to talk *to the user*?

# /dev/tty vs. /dev/cons

```
% (process_foo <foo >bar ) >&errs
```

- csh-speak for
  - Run “process\_foo”
  - Standard input is “foo”
  - Standard output sent to “bar”
  - Standard error sent to “errs”

“process\_foo” is pretty well connected to *files*

- What if it wants to talk *to the user?*

**Unix solution –magic device “/dev/tty”**

- Rummages through your process, guesses your terminal
  - See O\_NOCTTY flag to open(2), see vhangup(2)-or don't...
- Opens /dev/ttyXX for you, returns that

# /dev/tty vs. /dev/cons

```
% (process_foo <foo >bar ) >&errs
```

What if process\_foo wants to talk *to the user*?

Plan 9 –your *namespace* contains /dev/cons

- The right device is *mounted* as /dev/cons
- By whoever runs you
  - window manager, login, remote login
- Unix question: what is the name of the terminal I'm running on? tty7? ttyq9?
- Plan 9 answer: whoever connected you to your terminal arranged for it to have the conventional name - /dev/cons

# /dev/tty vs. /dev/cons

## Unix remote login

- /dev/tty delegates to /dev/ttyp1
  - “pseudo-tty” - careful emulation of a serial line
- master (/dev/ptyp1) is managed by sshd
- ASCII characters flow across the network
- Your ssh client is running on /dev/ttyq3
  - Which is connected to a screen window by “xterm”
- What happens when you resize your xterm??

## Plan 9 remote login

- Shell's /dev/cons is a *remote file mount* of a window
- Same as if the window were local (albeit slower)

# Per-Window Devices

## X: a complex monolithic server somewhere

- House of a thousand mysteries
- **Not** on the 15-410 reading list: ICCCM
  - “Inter-client communication conventions manual”

## Plan 9: Per-window devices

- I/O - /dev/mouse, /dev/cursor, /dev/cons
- Contents - /dev/text, /dev/window
- Window title - /dev/label (a 1-line text file)
- Working directory - /dev/wdir

```
% echo top > /dev/wctl
```

- Requests window manager to bring your window to top

# *Per-Window* Devices

## **Screen shot**

```
% cp /dev/screen /tmp/screen-image
```

## **Window shot**

```
% cp /dev/window /tmp/window-image
```

# The Serial-Port File System

**Look, Ma, no ioctl()!**

```
% bind -a '#t' /dev
```

```
% echo b9600 > /dev/eia1ctl
```

```
% echo "foo" > /dev/eia1
```

# The CD-Burner File System

## Burn audio tracks to CD

```
% cdfs -d /dev/sdD0
```

- Uses /dev/sdD0/raw to send SCSI commands to disk
- Mounts itself as /mnt/cd in your namespace

```
% cp *.cda /mnt/cd/wa/
```

- Write CD-Audio tracks to “write audio” directory

```
% rm /mnt/cd/wa
```

- Remove writing directory to close session

```
% echo eject > /mnt/cd/ctl
```

# The tar-ball File System

## Rummage through a tar file

```
% fs/tarfs -m /n/tarball foo.tar  
% cat /n/tarball/README
```

# The TCP File System

## Look, Ma, no finger command!

```
#!/bin/rc
# hold clone & ctl open during connection
{ conn=`{read} cd /net/tcp/$conn
  { echo 'connect 128.2.194.80!79' > ctl ;
    echo davide > data; cat data } < ctl
} < /net/tcp/clone
```

## Look, Ma, no NAT proxy setup!

```
% import gateway.srv /net/tcp
```

# The /tmp Problem

**Unix /tmp: security hole generator**

**Programs write /tmp/program.3802398**

- Or /tmp/program.\$USER.3432432

**No name collision “in practice”**

- Unless *an adversary* is doing the practicing  
% ln -s /tmp/program.3802398 /.cshrc
- Now a setuid-root program will put your commands into root's .cshrc...

# Fixing /tmp

**No inter-user security problem if *only one user!***

**Plan 9 /tmp is per-user**

- User chooses what backs the /tmp name
  - Temporary “RAM disk” file system?
  - /usr/\$user/tmp

**Matches (sloppy) programmer mental model**

# Plan 9 3-Level File Store

## Exports one tree spanning many disks

- Users bind parts of the tree into namespaces

## Original implementation –3-level store

- RAM caches disks, disks cache WORM jukebox

## Plug-compatible modern implementation

- Hash-capability log-structured disk store

## Daily snapshots, available forever

- `/n/dump/1995/0315` is 1995-03-15 snapshot
- Time travel without “restoring from tape”
  - Public files are *eternally* public –be careful!

# Plan 9 Process Model

## New-process model

- `fork()/mount()/exec()`

## System calls block

## Task/thread continuum via `rfork()`

- Resources are shared/copied/blank
  - Namespace, environment strings
  - File descriptor table, memory segments, notes
  - Rendezvous space
- `rfork()` w/o “new process” bit edits current process

# Process Synchronization

## **rendezvous(tag, value)**

- Sleeps until a 2<sup>nd</sup> process presents matching tag
- Two processes swap values
- “Tag space” sharing via rfork() like other resources

## **Shared-memory spin-locks**

# Summary

## Files, files, files

- “Plumber” paper
  - Programmable file server
  - Parses strings, extracts filenames
  - Sends filenames to programs
  - File, file, blah, blah, ho hum?
- Isn't it cleaner than
  - Sockets, ICCCM, RPC program numbers, CORBA?

## Not just another reimplementation of 1970

- Every compile is a cross-compile
- Every debug is a remote cross-platform debug
- Unicode everywhere
- ...

# More Information

## **“Gold Server” multi-computer environment approach**

- How to build a system out of a bunch of Unixes
- Similar approach to Andrew
- Difficult
- <http://www.infrastructures.org/papers/bootstrap/>

## **Plan 9**

- <http://www.cs.bell-labs.com/plan9/>

# Disclaimer

**A distributed system is a system in which I can't do my work because some computer has failed that I've never even heard of.**

- Leslie Lamport
