Principles of Software Construction: Objects, Design, and Concurrency

Testing and Invariants

The four course themes

- **Threads and Concurrency**
  - Concurrency is a crucial system abstraction
  - E.g., background computing while responding to users
  - Concurrency is necessary for performance
  - Multicore processors and distributed computing
  - Our focus: application-level concurrency
  - Cf. functional parallelism (150, 210) and systems concurrency (213)

- **Object-oriented programming**
  - For flexible designs and reusable code
  - A primary paradigm in industry – basis for modern frameworks
  - Focus on Java – used in industry, some upper-division courses

- **Analysis and Modeling**
  - Practical specification techniques and verification tools
  - Address challenges of threading, correct library usage, etc.

- **Design**
  - Proposing and evaluating alternatives
  - Modularity, information hiding, and planning for change
  - Patterns: well-known solutions to design problems
Learning Goals

- Different strategies of quality assurance, different meanings of quality
- Importance of specifications (formal or informal)
- Testing approaches, benefits, and limitations
- Unit testing
  - Ability to use JUnit
- Test coverage: what it tells you, what it doesn’t
  - Ability to use EclEmma for line coverage
- Class invariants and assertions
Correctness?
Software Quality

- **Sufficiency**
  - Fails to implement the specifications ... Satisfies all of the specifications

- **Robustness**
  - Will crash on any anomalous even ... Recovers from all anomalous events

- **Flexibility**
  - Will have to be replaced entirely if specification changes ... Easily adaptable to reasonable changes

- **Reusability**
  - Cannot be used in another application ... Usable in all reasonably related applications without modification

- **Efficiency**
  - Fails to satisfy speed or data storage requirement ... satisfies speed or data storage requirement with reasonable margin

- **Reliability**
  - Won't achieve required mean time between failure ... will achieve the required mean time between failure

- **Scalability**
  - Cannot be used as the basis of a larger version ... is an outstanding basis...

- **Security**
  - Security not accounted for at all ... No manner of breaching security is known

public int read(byte[] b, int off, int len) throws IOException

- Reads up to len bytes of data from the input stream into an array of bytes. An attempt is made to read as many as len bytes, but a smaller number may be read. The number of bytes actually read is returned as an integer. This method blocks until input data is available, end of file is detected, or an exception is thrown.
- If len is zero, then no bytes are read and 0 is returned; otherwise, there is an attempt to read at least one byte. If no byte is available because the stream is at end of file, the value -1 is returned; otherwise, at least one byte is read and stored into b.
- The first byte read is stored into element b[off], the next one into b[off+1], and so on. The number of bytes read is, at most, equal to len. Let \( k \) be the number of bytes actually read; these bytes will be stored in elements b[off] through b[off+k-1], leaving elements b[off+k] through b[off+len-1] unaffected.
- In every case, elements b[0] through b[off] and elements b[off+len] through b[b.length-1] are unaffected.

- **Throws:**
  - IOException - If the first byte cannot be read for any reason other than end of file, or if the input stream has been closed, or if some other I/O error occurs.
  - NullPointerException - If b is null.
  - IndexOutOfBoundsException - If off is negative, len is negative, or len is greater than b.length - off
Specifications

- **Contains**
  - Functional behavior
  - Erroneous behavior
  - Quality attributes

- **Desirable attributes**
  - Complete
    - Does not leave out any desired behavior
  - Minimal
    - Does not require anything that the user does not care about
  - Unambiguous
    - Fully specifies what the system should do in every case the user cares about
  - Consistent
    - Does not have internal contradictions
  - Testable
    - Feasible to objectively evaluate
  - Correct
    - Represents what the end-user(s) need
Function Specifications

- A function’s contract is a statement of the responsibilities of that function, and the responsibilities of the code that calls it.
  - Analogy: legal contracts
    - If you pay me $30,000
    - I will build a new room on your house
  - Helps to pinpoint responsibility

- Contract structure
  - Precondition: the condition the function relies on for correct operation
  - Postcondition: the condition the function establishes after correctly running

- (Functional) correctness with respect to the specification
  - If the client of a function fulfills the function’s precondition, the function will execute to completion and when it terminates, the postcondition will be fulfilled

- What does the implementation have to fulfill if the client violates the precondition?
int total(int array[], int len);

/*@ requires len >= 0 && array != null && array.length == len; @
@ ensures \result == \sum int j; 0 <= j && j < len; array[j]); @*/

Textual Specifications

List:

**boolean addAll(int index, Collection<? extends E> c)**

Inserts all of the elements in the specified collection into this list at the specified position (optional operation). Shifts the element currently at that position (if any) and any subsequent elements to the right (increases their indices). The new elements will appear in this list in the order that they are returned by the specified collection's iterator. The behavior of this operation is undefined if the specified collection is modified while the operation is in progress. (Note that this will occur if the specified collection is this list, and it's nonempty.)

**Parameters:**
- index - index at which to insert the first element from the specified collection
- c - collection containing elements to be added to this list

**Returns:**
- true if this list changed as a result of the call

**Throws:**
- `UnsupportedOperationException` - if the addAll operation is not supported by this list
- `ClassCastException` - if the class of an element of the specified collection prevents it from being added to this list
- `NullPointerException` - if the specified collection contains one or more null elements and this list does not permit null elements, or if the specified collection is null
- `IllegalArgumentException` - if some property of an element of the specified collection prevents it from being added to this list
- `IndexOutOfBoundsException` - if the index is out of range (index < 0 || index > size())

Runtime Checking of Specifications

/*@ requires len >= 0 && array.length == len 
  @ ensures \result == \sum int j; 0 <= j && j < len; array[j] 
  @*/
float sum(int array[], int len) {
  assert len >= 0;
  assert array.length == len;
  float sum = 0.0;
  int i = 0;
  while (i < len) {
    sum = sum + array[i]; i = i + 1;
  }
  return sum;
  assert ...;
}

float sum(int array[], int len) {
    if (len < 0 || array.length != len)
        throw IllegalArgumentException(...);
    float sum = 0.0;

    return sum;
assert ...;
}

Check arguments even when assertions are disabled. Good for robust libraries!
