Principles of Software Construction: Objects, Design and Concurrency

Design: GRASP and Refinement

Jonathan Aldrich  Charlie Garrod

Object Design

• “After identifying your requirements and creating a domain model, then add methods to the software classes, and define the messaging between the objects to fulfill the requirements.”

• But how?
  ▪ What method belongs where?
  ▪ How should the objects interact?
  ▪ This is a critical, important, and non-trivial task
The GRASP patterns are a learning aid to
- help one understand essential object design
- apply design reasoning in a methodical, rational, explainable way.

This approach to understanding and using design principles is based on patterns of assigning responsibilities
GRASP - Responsibilities

• Responsibilities are related to the obligations of an object in terms of its behavior.

• Two types of responsibilities:
  ▪ knowing
  ▪ doing

• Doing responsibilities of an object include:
  ▪ doing something itself, such as creating an object or doing a calculation
  ▪ initiating action in other objects
  ▪ controlling and coordinating activities in other objects

• Knowing responsibilities of an object include:
  ▪ knowing about private encapsulated data
  ▪ knowing about related objects
  ▪ knowing about things it can derive or calculate
GRASP

• Name chosen to suggest the importance of grasping fundamental principles to successfully design object-oriented software

• Acronym for General Responsibility Assignment Software Patterns

• Describe fundamental principles of object design and responsibility

• General principles, may be overruled by others
Fred: "Where do you think we should place the responsibility for creating a SalesLineItem? I think a Factory."

Wilma: "By Creator, I think Sale will be suitable."

Fred: "Oh, right - I agree."
Nine GRASP Principles:

- Low Coupling
- High Cohesion
- Information Expert
- Creator
- Controller
- Polymorphism
- Indirection
- Pure Fabrication
- Protected Variations
Low Coupling Principle

Problem:
How to increase reuse and decrease the impact of change.

Solution:
Assign responsibilities to minimize coupling.

Use this principle when evaluating alternatives.
Example

• Create a Payment and associate it with the Sale.
Example

```
makePayment()

: Register

1: create()

p : Payment

2: addPayment(p)

: Sale
```

Example:

```makePayment()
: Register
1: create()
p : Payment
2: addPayment(p)
: Sale```
Example:

```
makePayment() : Register 1: create() → p : Payment

2: addPayment(p) → :Sale
```

```
makePayment() : Register 1: makePayment() → :Sale

1.1. create() → :Payment
```
Second solution has less coupling
Register does not know about Payment class
Why High Coupling is undesirable

• Coupling is a measure of how strongly one element is connected to, has knowledge of, or relies on other elements.

• An element with low (or weak) coupling is not dependent on too many other elements (classes, subsystems, ...)
  ▪ "too many" is context-dependent

• A class with high (or strong) coupling relies on many other classes.
  ▪ Changes in related classes force local changes.
  ▪ Such classes are harder to understand in isolation.
  ▪ They are harder to reuse because its use requires the additional presence of the classes on which it is dependent.
Low Coupling

• Benefits of making classes independent of other classes
  ▪ changes are localised
  ▪ easier to understand code
  ▪ easier to reuse code
Common Forms of Coupling in OO Languages

- TypeX has an attribute (data member or instance variable) that refers to a TypeY instance, or TypeY itself.

- TypeX has a method which references an instance of TypeY, or TypeY itself, by any means.
  - Typically include a parameter or local variable of type TypeY, or the object returned from a message being an instance of TypeY.

- TypeX is a direct or indirect subclass of TypeY.

- TypeY is an interface, and TypeX implements that interface.
Low Coupling: Discussion

- Low Coupling is a principle to keep in mind during all design decisions
- It is an underlying goal to continually consider.
- It is an evaluative principle that a designer applies while evaluating all design decisions.
- Low Coupling supports the design of classes that are more independent
  - reduces the impact of change.
- Can't be considered in isolation from other patterns such as Expert and High Cohesion
- Needs to be included as one of several design principles that influence a choice in assigning a responsibility.
Low Coupling: Discussion

• Subclassing produces a particularly problematic form of high coupling
  ▪ Dependence on implementation details of superclass
  ▪ -> Prefer composition over inheritance

• Extremely low coupling may lead to a poor design
  ▪ Few incohesive, bloated classes do all the work; all other classes are just data containers

• Contraindications: High coupling to very stable elements is usually not problematic
High Cohesion Principle

Problem:
How to keep complexity manageable.

Solution:
Assign responsibilities so that cohesion remains high.

Cohesion is a measure of how strongly related and focused the responsibilities of an element are.

An element with highly related responsibilities, and which does not do a tremendous amount of work, has high cohesion.
High cohesion

- Classes are easier to maintain
- Easier to understand
- Often support low coupling
- Supports reuse because of fine grained responsibility
Except for cohesion), looks OK if \textit{makePayment} considered in isolation, but adding more system operations, \textit{Register} would take on more and more responsibilities and become less cohesive.
Example

makePayment() : Register

1: create()

p : Payment

2: addPayment(p)

: Sale

makePayment() : Register

1: makePayment()

: Sale

1.1. create()

: Payment

makePayment() : Register

: Sale

: Payment
Extra: isVisited

class Graph {
    Node[] nodes;
    boolean[] isVisited;
}
class Algorithm {
    int shortestPath(Graph g, Node n, Node m) {
        for (int i; ...)
            if (!g.isVisited[i]) {
                ...
                g.isVisited[i] = true;
            }
        return v;
    }
}
High Cohesion: Discussion

• **Scenarios:**
  - Very Low Cohesion: A Class is solely responsible for many things in very different functional areas.
  - Low Cohesion: A class has sole responsibility for a complex task in one functional area.
  - High Cohesion: A class has moderate responsibilities in one functional area and collaborates with other classes to fulfil tasks.

• **Advantages:**
  - Classes are easier to maintain
  - Easier to understand
  - Often support low coupling
  - Supports reuse because of fine grained responsibility

• **Rule of thumb:** a class with high cohesion has a relatively small number of methods, with highly related functionality, and does not do too much work.
Information Expert Principle

- Who should be responsible for **knowing** the grand total of a sale?
Problem: What is a general principle of assigning responsibilities to objects?

Solution: Assign a responsibility to the information expert, the class that has the information necessary to fulfill the responsibility.

Start assigning responsibilities by clearly stating responsibilities!

Typically follows common intuition

Design Classes (Software Classes) instead of Conceptual Classes
  - If Design Classes do not yet exist, look in Domain Model for fitting abstractions (-> low representational gap)
What information is needed to determine the grand total?

- Line items and the sum of their subtotals

Sale is the information expert for this responsibility.

```getTotal()```
To fulfill the responsibility of knowing and answering the sale's total, three responsibilities were assigned to three design classes of objects.

<table>
<thead>
<tr>
<th>Design Class</th>
<th>Responsibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sale</td>
<td>knows sale total</td>
</tr>
<tr>
<td>SalesLineItem</td>
<td>knows line item subtotal</td>
</tr>
<tr>
<td>ProductSpecification</td>
<td>knows product price</td>
</tr>
</tbody>
</table>
Information Expert

New method

Sale
  time ...
  getTotal()

SalesLineItem
  quantity
  getSubtotal()

Product
  Description
  description
  price
  itemID
  getPrice()

:Product
Description

1.1: p := getPrice()

1 *: st = getSubtotal

: Sale

t = getTotal

: SalesLineItem

lineItems[i] : SalesLineItem
Information Expert -> "Do It Myself Strategy"

- Expert usually leads to designs where a software object does those operations that are normally done to the inanimate real-world thing it represents
  - a sale does not tell you its total; it is an inanimate thing

- In OO design, all software objects are "alive" or "animated," and they can take on responsibilities and do things.

- They do things related to the information they know.
• **Contraindication: Conflict with separation of concerns**
  - Example: Who is responsible for saving a sale in the database?
  - Adding this responsibility to Sale would distribute database logic over many classes $\rightarrow$ low cohesion

• **Contraindication: Conflict with late binding**
  - Late binding is available only for the receiver object
  - But maybe the variability of late binding is needed in some method argument instead
    - So make the argument the receiver instead
    - Example: use a strategy pattern to compute the total. Different strategies may capture special discounts, for example.
Creator Principle: Problem

• Who creates Nodes in a Graph?
• Who creates instances of SalesLineItem?
• Who creates Rabbit-Actors in a Game?
• Who creates Tiles in a Monopoly game?
  • AI? Player? Main class? Board? Meeple (Dog)?
Who creates Tiles in a Monopoly game?

- Typical Answer: The board
- Container creates things contained
Creator Principle

• Assign class B responsibility of creating instance of class A if
  ▪ B aggregates A objects
  ▪ B contains A objects
  ▪ B records instances of A objects
  ▪ B closely uses A objects
  ▪ B has the initializing data for creating A objects

• where there is a choice, prefer
  ▪ B aggregates or contains A objects

• Key idea: Creator needs to keep reference anyway and will frequently use the created object
• Who is responsible for creating SalesLineItem objects?
Creator : Example

- Creator pattern suggests Sale.

- Sequence diagram is
• Promotes low coupling by making instances of a class responsible for creating objects they need to reference

• By creating the objects themselves, they avoid being dependent on another class to create the object for them

• Contraindications:
  ▪ creation may require significant complexity, such as
    ▪ using recycled instances for performance reasons
    ▪ conditionally creating an instance from one of a family of similar classes based upon some external property value
  ▪ Sometimes desired to outsource object wiring ("dependency injection")
Controller Principle

Problem:

Who should be responsible for handling an input system event?

Solution:

Assign the responsibility for receiving or handling a system event message to a class representing the overall system, device, or subsystem (facade controller) or a use case scenario within which the system event occurs (use case controller)
Controller: Example

Which class of object should be responsible for receiving this system event message?

- It is sometimes called the controller or coordinator. It does not normally do the work, but delegates it to other objects.
- The controller is a kind of "facade" onto the domain layer from the interface layer.
By the Controller pattern, here are some choices:

- **Register, POSSystem**: represents the overall "system," device, or subsystem
- **ProcessSaleSession, ProcessSaleHandler**: represents a receiver or handler of all system events of a use case scenario
Controller: Discussion

• Normally, a controller should delegate to other objects the work that needs to be done; it coordinates or controls the activity. It does not do much work itself.

• Facade controllers are suitable when there are not "too many" system events.

• A use case controller is an alternative to consider when placing the responsibilities in a facade controller leads to designs with low cohesion or high coupling.
  ▪ typically when the facade controller is becoming "bloated" with excessive responsibilities.
Controller: Discussion

• **Benefits**
  - Increased potential for reuse, and pluggable interfaces
    - No application logic in the GUI
  - Dedicated place to place state that belongs to some use case
    - E.g. operations must be performed in a specific order

• **Avoid bloated controllers!**
  - E.g. single controller for the whole system, low cohesion, lots of state in controller
  - Split into use case controllers, if applicable

• **Interface layer does not handle system events**
From Design to Implementation

• Use Design Model as roadmap for implementation

• Decision making and creativity still required
  ▪ Models typically incomplete at first
  ▪ Models foster better understanding and help making better implementation decisions

• Start with class with least dependencies

```java
public class SalesLineItem {
    private int quantity;
    private ProductDescription description;
    public SalesLineItem(ProductDescription desc, int qty) { ... }
    public Money getSubtotal() { ... }
}
```
Implementing Associations

class X {
    Y a;
}
class Y {
    X a;
}

---

class X {
    List<Y> a;
}
class Y {
    X a;
}

---

class X {
    Y a;
}
class Y {}
A Design Technique: CRC Cards

- **Class-Responsibility-Collaboration**
  - Name of class
  - Responsibilities/functionality of the class
  - Other classes it invokes to achieve that functionality

- **Responsibility guidelines**
  - Spread out functionality
    - No “god” classes – make maintenance difficult
  - State responsibilities generally
    - More reusable, more abstract
  - Group behavior with related information
    - Enhances cohesion, reduces coupling
    - Promotes information hiding of data structures
  - Information about one thing goes in one place
    - Spreading it out makes it hard to track
CRC Validation

- **Validation**
  - Ensure all functionality in specification is covered by some class
  - Reason through how functionality could be achieved
    - Abstractly executing the program
    - What other classes are needed?
    - Are their responsibilities enough for this class to do what it needs to do?

- **Refine as needed**
Refining a Design

• **Step through Use Cases**
  - Verify completeness of diagram by asking:
    - Which methods execute?
    - What methods are called?
    - What does each method or object have to know?

• **Consider quality attributes**
  - Make concrete with a test
    - e.g. modification scenario, performance target
  - Generate multiple designs – not just one
    - What design patterns achieve this attribute?
    - May be helpful to have different people develop designs independently
  - Evaluate designs
    - How well does this design achieve the entire set of quality attributes?
    - May require prioritizing attributes
Design Principles: Information Hiding

• (see other deck)
Summary: Phases and Terminology

- **Conceptual Modeling / Object-Oriented Analysis**
  - Create **Domain Model** / Conceptual Model
  - Analyzing the Domain, Vocabulary for further Design
  - Visualization of the concepts or mental models of a real-world domain
  - UML for sketching (conceptual perspective)

- **Object-Oriented Design**
  - **Design Model** / Object Model / Design Class Diagrams
  - Classes, Objects and their behavior and relationships
  - UML as a blueprint (specification perspective)

- **Implementation**
  - Mapping Designs to Code
  - Implementing classes and methods
  - (Code generation; UML as a programming language; implementation perspective)
Summary

• Design requires tradeoffs

• Conceptual modeling to understand domain
  § UML as visual language

• GRASP Principles for first design considerations
  § Information Expert
  § Creator
  § Low Coupling, High Cohesion
  § Controller
  - Chapter 9 introduces conceptual modeling
  - Chapter 16+17+22 introduce GRASP

  - Chapter 3 and 4 discuss Design Goals and Modularity
Goals for Object Design
A software construction method satisfies Modular Decomposability if it helps in the task of decomposing a software problem into a small number of less complex subproblems, connected by a simple structure, and independent enough to allow further work to proceed separately on each of them.
Five Criteria: Modular Decomposability

- **POS Example:**
  - Data Model
  - User Interface
  - Printing Receipts
  - Tax Accounting
  - Admin Interface
  - Connecting Scales...

- Modular Decomposability implies: Division of Labor possible!
A method satisfies Modular Composability if it favors the products of software elements which may then be freely combined with each other to produce new systems, possibly in an environment quite different from the one in which they were initially developed.
Five Criteria: Modular Composability

- Is dual to modular decomposability
- Is directly connected with reusability
- Example 1: Libraries have been reused successfully in countless domains
- Example 2: Unix Shell Commands
- **POS: Examples:**
  - Reuse existing Storage Management System
  - Connect to CRM System
- **Counter-Example:** Preprocessors
A method favors Modular Understandability if it helps produce software in which a human reader can understand each module without having to know the others, or, at worst, by having to examine only a few of the others.
Five Criteria: Modular Understandability

• Important for maintenance
• Applies to all software artifacts, not just code
• Counter-example: Sequential dependencies between modules
Five Criteria: Modular Continuity

A method satisfies Modular Continuity if, in the software architectures that it yields, a small change in the problem specification will trigger a change of just one module, or a small number of modules.
Five Criteria: Modular Continuity

• POS: Examples
  ▪ Change currency, taxes
  ▪ Change used printer

• Example 1: Symbolic constants (as opposed to magic numbers)

• Example 2: Hiding data representation behind an interface

• Counter-Example: Program designs depending on fragile details of hardware or compiler
A method satisfied Modular Protection if it yields architectures in which the effect of an abnormal condition occurring at run time in a module will remain confined to that module, or at worst will only propagate to a few neighboring modules.
Five Criteria: Modular Protection

• Motivation: Big software will always contain bugs etc., failures unavoidable

• POS Example:
  - Printer crashes
  - Scanned item is unknown

• Example: Defensive Programming

• Counter-Example: An erroneous null pointer in one module leads to an error in a different module
The modular structure devised in the process of building a software system should remain compatible with any modular structure devised in the process of modeling the problem domain.

Follows from continuity and decomposability
A Payment in the Domain Model is a concept, but a Payment in the Design Model is a software class. They are not the same thing, but the former inspired the naming and definition of the latter.

This reduces the representational gap.

This is one of the big ideas in object technology.

The object-oriented developer has taken inspiration from the real world domain in creating software classes.

Therefore, the representational gap between how stakeholders conceive the domain, and its representation in software, has been lowered.
Every module should communicate with as few others as possible
Five Rules: Few Interfaces

- Want topology with few connections
- Follows from continuity and protection; otherwise changes/errors would propagate more
If two modules communicate, they should exchange as little information as possible.
Five Rules: Small Interfaces

• Follows from continuity and protection, required for composability

• Counter-Example: Big Interfaces 😊
Whenever two modules A and B communicate, this must be obvious from the interface of A or B or both.
Five Rules: Explicit Interfaces

- Counter-Example 1: Global Variables
- Counter-Example 2: Aliasing – mutation of shared heap structures
Intermezzo: Law of Demeter (LoD)

- LoD (or Principle of Least Knowledge): Each module should have only limited knowledge about other units: only units "closely" related to the current unit
- In particular: Don’t talk to strangers!
- For instance, no a.getB().getC().foo()
- Motivated by low coupling
The designer of every module must select a subset of the module’s properties as the official information about the module, to be made available to authors of client modules.
Five Rules: Information Hiding
class Player {
    Board board;
    Square getSquare(String name) {
        for (Square s: board.getSquares())
            if (s.getName().equals(name))
                return s;
    }

    return null;
}

class Board{
    List<Square> squares;
    Square getSquare(String name) {
        for (Square s: squares)
            if (s.getName().equals(name))
                return s;
    }

    return null;
}
Summary Design Goals

- Modular Decomposability
- Modular Composability
- Modular Understandability
- Modular Continuity
- Modular Protection
- Direct Mapping / Low Representational Gap
- Few Interfaces
- Small Interfaces
- Explicit Interfaces
- Information Hiding
