DevOps: Engineering for Secure Development and Deployment

Jonathan Aldrich, Professor

Course Staff

- Jonathan Aldrich
 - CMU professor since 2003
 - Was co-founder/CTO of Noteful, a startup developing an app teaching music reading and theory
 - Directs MSE program since July 2025
 - Research: currently designing Meerkat, a DevOps programming language
 - Saul Alvarez Tapia, TA
-

Deployment and Operations for Software Engineers 2nd Ed

Chapter 9 – What is DevOps?

A story from last night

Outline

- **Introduction**
 - Motivation
 - Introduction to technical aspects
 - Culture
 - Organization
 - Metrics
-

DevOps

- DevOps is a combination of Development and Operations. The original intent was to break down walls between the two groups.
- Historically,
 - developers would deliver completed systems to operations
 - Operations would then be responsible for provisioning hardware and running the system
 - Caused tensions
- Recently the term DevSecOps has been used to indicate that security should be considered in DevOps activities

Definition

- “a set of practices that aims to shorten the systems development life cycle and provide continuous delivery with high software quality” – Wikipedia
 - Definition ignores continuous deployment
 - **Continuous deployment** – automated testing, automatic deployment after developer commits
 - **Continuous delivery** – automated testing, deployment decision is manual. Regulations may require human sign off on deployment decisions
-

DevOps decomposition

Discussion questions

1. Have you used a DevOps tool? Which one? Does it fit the definition?
2. These days, Kubernetes is considered a DevOps tool. How does Kubernetes reduce the time to production?

Outline

- Introduction
 - **Motivation**
 - Introduction to technical aspects
 - Culture
 - Organization
 - Metrics
-

Breaking down barriers is not enough

- It takes investments of time and money to implement DevOps
 - Organizations must be convinced that they will recoup their investment.
 - Two classes of payoffs
 - Reducing the time between the committing of code by the developers – code complete--and the placing of that code into production – deployment time.
 - Reducing the time to detect and repair problems after the code goes into production – incident handling.
-

Traditional process for constructing or modifying large systems

- Developers are divided into teams.
 - A new function or modification to an existing function is analyzed by the project management and portions are allocated to one or more teams.
 - Each team develops their portion according to predefined project processes and checks the results into a version control system.
 - After all of the teams have completed their portion, the portions are integrated into a complete executable, tested, and placed into production.
-

Sources of delay - processes

- Defining project processes takes time.
 - Agreement must be reached on
 - a common language,
 - versions of libraries,
 - interfaces,
 - supporting tooling,
 - coordination processes.
 - Getting this agreement takes time, documenting the agreement takes time, and not all teams will remember or abide by the agreements.
-

Sources of delay - integration

- Incorrect use of interfaces,
- inconsistent library versions,
- inconsistencies in development environments .
- Integration cannot be completed until all the teams have finished their portion and until all third-party dependencies are available.

Sources of delay - testing

- The testers must define the test cases and their expected results.
- Manual testing takes time since humans are involved.

Sources of delay – errors in production

- access control
- Inconsistent configuration parameters
- inconsistencies between the development environment and the production environment.

Consequence of delays

- The time involved in deployment led to scheduled releases.
- Monthly, quarterly, or yearly were common.

Traditional incident handline

- An operator observed or was notified of the incident.
 - If repairing the incident was within the operator's ability, then it was repaired, a report was filed, and the system continued operations.
 - If repairing the incident was not possible for the operator,
 - a ticket describing the incident was filed
 - the ticket was routed to developers who then took responsibility for repairing the problem.
 - Diagnosing and repairing took time
 - For many problems, the repair was included in the next scheduled release.
-

Security incidents

- The number of security breaches has been increasing dramatically year to year.
- Over a third of such breaches are caused by configuration errors.
 - mistakes configuring the firewall
 - cloud systems and servers that were misconfigured

Discussion questions

- Which of the causes of delay in deployment have you experienced? How much time was spent identifying and repairing the errors?

DevOps processes

Release

Approve for deployment

Test

Ensure high test coverage & automate tests as much as possible

Build

Create an executable artifact

Dev

Perform normal development activities
Create scripts for other activities

Deploy

Move into production environment

Operate

Execute system and gather measurements about its operation

Monitor & Analyze

Display measurements taken during operation & analyze the data

Design

Design architecture to support other activities

Design

- The design must accommodate solutions to deployment problems and visibility for monitoring and analysis of the system in production.
- The design can also be subject to a security review

Development

- DevOps automation involves a collection of scripts, and these are, typically, created and maintained by the developers.
- Static analysis can examine code created for bad security practices
- Scanning tools can examine scripts for various security flaws.

Build

- An executable image is created automatically when code is checked into a version control system. Errors are returned to the developers.
- Tools can check whether any components have known vulnerabilities.

Test

- Tests should be automated. Errors are returned to the developers.
- Both functional and quality tests are executed.

Release

- Some domains require manual approval of a release. Others allow automatic release.

Deploy

- The executable image is placed in production.
- Access and authorization functions are in place.

Operate

- The system performs its functions. Data is collected while it is operating..
- Scanners can examine network connections and operation of some portions of the infrastructure for security purposes.

Monitoring and Analysis

- The data collected during operation is monitored and analyzed.
- This may result in architectural modifications which are performed by returning to the design stage.

Environments

- The Development, build, test, and operate stages all exist in their own environment.
- An *environment* is a collection of provisioned resources. The resources include an operating system, network connections, memory, CPU, and any software dependencies.

Discussion questions

1. The various stages of the pipeline—build, test, deploy—should gather measures about their actions. What measures should be gathered?
2. What are some types of quality tests that can be done on the built system?

Outline

- Introduction
 - Motivation
 - Introduction to technical aspects
 - **Culture**
 - Organization
 - Metrics
-

DevOps and Agile

- **Focus of movements**

- DevOps has a focus both on development and operations
- Agile has its focus on development.

- **Practice focus**

- Agile focusses on management practices such as Scrum, Kanban, etc.
- DevOps focuses on tools

- **Feedback**

- Agile obtains feedback from customers
 - DevOps obtains feedback from measuring the running system and the various practices.
-

Agile and DevOps commonalities

- Both sets of practices advocate a non-blaming, open, sharing culture.
 - All members of the team should have access to the same information
 - Communication channels provide for rapid sharing and feedback.
 - Periodic retrospectives are advocated by both groups and problems are analyzed for the underlying causes without finger pointing and personal comments.
-

DevOps specific cultural practices.

1. Mindset

- Automation – always be alert to the possibility of automation
- Measurement - self-service monitoring and alerting

2. Incentives. Incentives are adjusted so that Dev, Ops, and Sec all are incentivized to the same results. For example, uptime of new releases with no security breaches is a metric all can subscribe to and contribute to.

Discussion questions

1. In your organization, how are developers incentivized? How are operators incentivized? Is there a tension between those two sets of incentives?
2. Who are the DevOps stakeholders? Who are the Agile stakeholders?

Outline

- Introduction
 - Motivation
 - Introduction to technical aspects
 - Culture
 - **Organization**
 - Metrics
-

Responsibilities are “Shifting Left”

- “Shifting Left” in DevOps means that some people involved in early life cycle phases (i.e. developers) are performing tasks that traditionally were done later in the life cycle (e.g. incident handling, acquiring resources)
 - There is evidence that shifting left reduces costs. The earlier in the life cycle a problem is detected, the cheaper it is to fix it.
 - Shifting left will cause changes in organizational units and add new responsibilities to existing roles.
-

New and changed organizational units

- The quality assurance (QA) unit may disappear, or it may have its responsibilities altered.
 - DevOps practices call for automated testing.
 - Traditionally, the QA unit was responsible for creating and executing tests and deciding whether a system was suitable to be deployed.
 - With automated tests and automated deployment, the responsibilities of the QA unit are substantially reduced if not eliminated.
-

Incident handling

- A new unit may be created to deal with incident handling.
 - System Reliability Engineer (SREs) are the first responders when an incident occurs. They exist in a separate organizational unit that assumes responsibility for the reliability of systems.
 - Google initiated this unit, and it has been adopted in other organizations.
 - Meta (Facebook) has created a unit to perform Production Engineering. This unit's responsibilities are to “champion the Reliability, Scalability, Performance, and Security posture of production services.”
-

Creating tools

- A unit to manage and create tools has emerged in multiple organizations.
- Google and Netflix create their own tools and other organizations have a unit to manage their tool suite.

New and changed responsibilities

- Traditionally
 - the operations group was responsible for resource acquisition and management.
 - A development team would create a system and the operations team would acquire resources to operate that system.
 - Developers now have responsibility for allocating resources and for reviewing and acting upon the monitoring information collected from operating the system.
-

New and changed responsibilities

- One model for incident handling is “You built it, you run it”. This model, introduced by Amazon, makes developers the first responders in the case of an incident.

Open System Model

- Microsoft and Alibaba Cloud have announced the “Open System Model” which defines responsibilities for developers and operators in terms of platform-based tools
 - Developer builds systems in containers
 - System operator packages and deploys containers
 - Infrastructure operator tunes as necessary at run time.

Discussion questions

1. Can you think of other roles affected by Shifting Left?
2. Will the ratios of developers to operators to security personnel change as a result of Shifting Left?

Outline

- Introduction
 - Motivation
 - Introduction to technical aspects
 - Culture
 - Organization
 - **Metrics**
-

Metrics

- A process improvement effort must be able to measure whether the changes it introduces have a positive impact.
 - Choosing the correct metrics is important since emphasizing the wrong metrics will lead to incorrect behavior.
 - Also, having too many metrics makes it difficult to optimize any single one.
-

DORA metrics

- DORA (DevOps Research and Assessment) proposes the following four metrics that have become widely adopted.
 1. Lead time for changes
 2. Change failure rate
 3. Deployment frequency
 4. Mean time to recovery

Lead time for changes.

- Length of time between committing a code change to the trunk branch and when it is in a deployable state.

Change failure rate

- .Percentage of code changes that require hot fixes or other remediation after production. This does not measure failures caught by testing and fixed before code is deployed.

Deployment frequency

- The number of deployments into production per unit time. For example, Amazon reports thousands of deployments per day.

Mean time to recovery

- .Mean time to recovery (MTTR) measures how long it takes to recover from a partial service interruption or total failure.

Discussion questions

1. How are each of the DORA metrics collected.
2. Which organization role is interested in the results of each metric.

Course Topics

- Background: Platforms, Networking, Cloud
 - Partly review for some, but we'll go quickly
 - Important basis to build on
 - Fundamentals: Virtualization, Containers, Configuration Management, Measurement, Observability
 - Development: Continuous integration and deployment, Infrastructure as code
 - Security: Infrastructure, DevSecOps, Secret Management
 - Agentic AI Ops (new!)
-

Course Overview

- Theory and practice
 - Theory will be presented via readings, and discussion
 - Practice will be through assignments
 - Evaluation –
 - Quizzes – 20%
 - Assignments – 70%
 - In-class participation – 10%
-

Course Materials

- Almost everything is on the course web page
 - <https://www.cs.cmu.edu/~aldrich/courses/17-636/>
 - Textbook: Deployment and Operations for Software Engineers
 - Buy or download from author's site
 - Supplemented with slides/course notes
 - Hand in assignments on Canvas
 - Questions on Piazza
-

First Assignment due Monday

- May 18, 11:59pm EDT
- Goal: build and run a small LLM on your machine, reflect on the challenges you observe

Read the Syllabus

- Course schedule and information
 - Late day policy: 5 free late days
 - Collaboration policy
 - Your work must be your own
 - AI use is OK, but you must understand your answers to get credit for them. We will assess this with semi-random interviews.
 - Accommodations
 - Take care of yourself!
-

Future class prep & agenda

- By noon EDT the day of class
 - Read chapter and/or watch lecture
 - Post 1 question to canvas discussion
 - During class
 - Discuss & supplement assigned material
 - Go over questions
 - Have further discussions
 - e.g. breakout rooms
-
