1 Introduction

Writing a compiler is a major undertaking. In this course, we will build not just one compiler, but several! Each compiler will build on the previous one, so careful thought and design are very important in the first labs. You will be re-using and re-writing code. To get you off to a good start, we provide you with a compiler for a simple language called $L1$. The compiler we have provided targets a very simple “abstract assembly” language with an infinite number of registers and a very simple instruction set which includes just arithmetic instructions. \footnote{There are some limitations to the starter code we give you. Please consult the last section on Supported Programming Languages for more on these.}

For this project, your task is to extend this compiler to translate $L1$ source programs into target programs written in actual x86-64 assembly language. To do this, the main changes that you will have to make are modifying the instruction selector and adding a register allocator. It must be possible to assemble and link the target programs (that is, the x86-64 assembly output from your compiler) with our runtime environment using gcc, producing a standard executable.

Projects should be done either individually or in pairs. You are strongly encouraged to work in teams of two. \footnote{There are certain circumstances under which working individually may be impractical. Once again, please consult the last section} Each team (or individual) is assigned a group name by the instructor. If you do not yet have a group name, please contact the instructor as soon as possible. You will not be able to download the starter code or hand in labs without accounts for the svn repository and the Autolab grading system, so you must have a group name.

The first project is neither the most difficult nor the most time consuming assignment in the course. The total amount of code you will have to write is not tremendously large. Nevertheless, as this is your first attempt at working with the compiler code, there is a relatively large amount of material to understand before you can get started, and you will also have to understand thoroughly the concepts of instruction selection and register allocation before attempting to implement anything.

In particular, keep in mind that all of the following may consume a substantial amount of time:

- Sorting out administrative problems. Making sure that you have svn and autolab access.
• Getting to know your partner. Working with a partner is an important aspect of this class. It is important to schedule time to work, find a preferred working environment, and develop a good group dynamic early in the semester. We strongly suggest that you schedule time for reading and discussing each other’s code at least twice weekly.

• Reading and possibly porting the entire starter code so that you understand every bit of what your compiler is doing. This is essential, because you will be editing every stage of the compiler in future labs, which will include any starter code that we distribute to you.

• Getting used to the libraries available for your programming language of choice. The libraries that your compiler depends on will likely include a parser combinator, LL(1) parser generator or LALR(1) parser generator, and possibly a separate lexer generator. Please make sure that you can find the specification documents for the libraries you use.

• Last, but certainly not the least, generating code requires attention to detail. Please be prepared to read through the Intel Developer Manuals for precise behaviour of the instructions you will emit, and the GNU assembler documentation for the syntax that you should use.

To emphasize again, all the projects in this course are cumulative. Therefore, falling behind in Lab 1 would be disastrous. Please get an early start, and remember that we’re here to help.

2 \textit{L1} Syntax

The compilers we provide to you translate source programs written in \textit{L1}. The syntax of \textit{L1} is defined by the context-free grammar shown in Figure 1. The language is a fragment of the C0 introductory programming language, and is similar to the “straight-line programs” language from Chapter 1 of the textbook.

\textbf{Lexical Tokens}

The concrete syntax of \textit{L1} is based on ASCII character encoding.

\textbf{Whitespace and Token Delimiting}

In \textit{L1}, whitespace is either a space, horizontal tab (\texttt{\textbackslash t}), vertical tab (\texttt{\textbackslash v}), carriage return (\texttt{\textbackslash r}), linefeed (\texttt{\textbackslash n}), or formfeed (\texttt{\textbackslash f}) character in ASCII encoding. Whitespace is ignored, except that it terminates tokens. For example, \texttt{+=} is one token, while \texttt{+ =} is two tokens.

\textbf{Comments}

\textit{L1} source programs may contain C-style comments of the form \texttt{/* \ldots */} for multi-line comments and \texttt{\//} for single-line comments. Multi-line comments may be nested (and of course the delimiters must be balanced).
The precedence of unary and binary operators is given in Figure 2.
Non-terminals are in ⟨brackets⟩.
Terminals are in bold.

Figure 1: Grammar of L1
<table>

</tbody>
</table>

Figure 2: Precedence of operators, from highest to lowest

```
<ident> ::= [A-Za-z_][A-Za-z0-9_]*
<num> ::= <decnum> | <hexnum>
<decnum> ::= 0 | [1-9][0-9]*
<hexnum> ::= 0[xX][0-9a-fA-F] +
<unop> ::= ! | ~ | - | *
<binop> ::= + | - | * | / | % | << | >>
        | < | > | == | != | & | ^ | | | && | || | >= | <=
<asnop> ::= = | += | -= | *= | /= | %= | <<= | >=
<postop> ::= -- | ++
```

Figure 3: Lexical Tokens

**Reserved Keywords**

The following are reserved keywords and cannot appear as a valid token in any place not explicitly mentioned as a terminal in the grammar.

```
struct typedef if else while for continue break
return assert true false NULL alloc alloc_array
int bool void char string
```

Many of these keywords are unused in L1. However, the specification treats these as keywords to maintain forward compatibility of valid C0 programs. For the purposes of L1, `main` shall also be treated as a keyword, since the language has no other concept of functions or function names.

**Other Tokens**

L1 also treats certain strings as tokens even though they never appear as terminals in the grammar. We do this in order to maintain forward compatibility with the remaining labs and C0. The tokens are listed in Figure 3.

Note that `postop` has higher precedence than `unop`. Therefore, we should first attempt to lex consecutive occurrences of `-` as the postfix decrement.
3  \textit{L1} Static Semantics

The \textit{L1} language does not have a very interesting type system. Most constraints imposed by the type system are for the time being imposed by the grammar instead.

Declarations

Though declarations are a bit redundant in a language with only one type and no interesting control flow construct, we require every variable in the function to be declared (with the correct type, in this case \texttt{int}) before being used, although statements and declarations can be mixed. We do this to ensure that the valid \textit{L1} programs are forward compatible with respect to future labs, and C0.

Initialization Checking

Programs that attempt to reference a variable before assigning to it should cause the compiler to generate a compile-time error message.

Return Checking

C0 requires that every control flow path in a function should be able to return. To maintain forward compatibility, we require that \textit{L1} programs contain a return statement, but not necessarily only once or at the last statement.

4  \textit{L1} Dynamic Semantics

Statements have the obvious operational semantics, although there are subtleties regarding the evaluation of expressions. Each statement is executed in turn. To execute a statement, the expression on the right-hand side of the assignment operator is evaluated, and then the result is assigned to the variable on the left-hand side, according to the type of assignment operator. The meanings of the special assignment operators are given by the following table, where \texttt{x} stands for any identifier and \texttt{e} for any expression.

\[
\begin{align*}
\texttt{x} & \texttt{+= e} & \equiv & \texttt{x} = \texttt{x} + \texttt{e} \\
\texttt{x} & \texttt{-=} e & \equiv & \texttt{x} = \texttt{x} - \texttt{e} \\
\texttt{x} & \texttt{*= e} & \equiv & \texttt{x} = \texttt{x} * \texttt{e} \\
\texttt{x} & \texttt{/=} e & \equiv & \texttt{x} = \texttt{x} / \texttt{e} \\
\texttt{x} & \texttt{\%=} e & \equiv & \texttt{x} = \texttt{x} \% \texttt{e}
\end{align*}
\]

The result of executing an \textit{L1} program is the value of the expression in the program’s \texttt{return} statement.

Integer Operations

The integers of this language are in two’s complement representation with a word size of 32 bits. Addition, subtraction, multiplication, and negation have their meaning as defined in arithmetic modulo $2^{32}$. In particular, they can never raise an overflow exception.

Decimal constants \texttt{c} in a program must be in the range $0 \leq c \leq 2^{31}$, where $2^{31} = -2^{31}$ according to modular arithmetic. Hexadecimal constants must fit into 32 bits.
The division $i/k$ returns the truncated quotient of the division of $i$ by $k$, dropping any fractional part. This means it always rounds towards zero.

The modulus $i \% k$ returns the remainder of the division of $i$ by $k$. The modulus has the same sign as $i$, and therefore

$$(i/k) \times k + (i \% k) = i$$

Division $i/k$ and modulus $i \% k$ are required to raise a divide exception if either $k = 0$ or the result is too large or too small to fit into a 32 bit word in two’s complement representation.

Fortunately, this prescribed behavior of integer operations coincides with the hardware behavior of appropriate instructions.

5 Project Requirements

For this project, you are required to hand in a complete working compiler for $L1$ that produces correct target programs written in Intel x86-64 assembly language. In addition to the code generator and the register allocator, you are also expected to modify the provided lexer so that it takes the reserved keywords and other lexical tokens into account.

We also require that you document your code. Documentation includes both inline documentation and a README document which explains the design decisions underlying the implementation along with the general layout of the sources. If you use publicly available libraries, you are required to indicate their use and source in the README file. If you are unsure whether it is appropriate to use external code, please discuss it with course staff.

When we grade your work, we will use the gcc compiler to assemble and link the code you generate into executables using the provided runtime environment on the lab machines.

Your compiler and test programs must be formatted and handed in via Autolab as specified below. For this project, you must also write and hand in at least six test programs, two of which must fail to compile, two of which must generate a runtime error, and two of which must execute correctly and return a value.

Test Files

Test files should have extension .l1 and start with one of the following lines

```
//test return i  program must execute correctly and return i
//test exception n program must compile but raise runtime exception n
//test error program must fail to compile due to an L1 source error
```

followed by the program text. The only exception defined in $L1$ is SIGFPE (8), which is raised upon division by zero or division overflow. All test files should be collected into a directory test/ (containing no other files) and submitted via the Autolab server.

This semester, 15-411 is using the new Autolab2 infrastructure. The Autolab handin for this course can be found at https://autolab.cs.cmu.edu/15411-f11

The reference compiler may display a warning on //test error if your test case accidentally exercises a language feature that might be a part of a future lab or C0. Please do not ignore this warning. Do not hand in tests that cause this warning.
Compiler Files

The files comprising the compiler itself should be collected in a directory `compiler/` which should contain a `Makefile`. **Important:** You should also update the `README` file and insert a description of your code and algorithms used at the beginning of this file. Even though your code will not be read for grading purposes, we may still read it to provide you feedback. The `README` file will be crucial information for that purpose.

Issuing the shell command

```
% make l1c
```

should generate the appropriate files so that

```
% bin/l1c <args>
```

will run your L1 compiler. If your compiler detects any (compile-time) errors in the source program, it should exit with a non-zero return code. If compilation succeeds and target code is generated, the compiler should then exit with a return code of 0. The command

```
% make clean
```

should remove all binaries, heaps, and other generated files.

Runtime Environment

Your target code will be linked against a very simple runtime environment. The runtime contains a function `main()` which calls a function `_l1_main` and then prints the returned value. If your compiler generates a target file called `foo.s`, it will be linked with the runtime into an executable using the command `gcc foo.s l1rt.c`. This means that your compiler must generate target code for a function called `_l1_main`, and that the `return` statement at the end of the L1 source program should be compiled into an x86 `ret` instruction. According to the calling conventions, the register `%eax` must hold the return value.

Using the Subversion Repository

The recommended method for handout and handin is the course subversion repository.

The handout files for this course can be checked out from our subversion repository via

```
% svn checkout https://cvs.concert.cs.cmu.edu/15411-f11/groups/<team>
```

where `<team>` is the name of your team. You will find materials for this lab in the `lab1` subdirectory. Or, if you have checked out `15411-f11/groups/<team>` directory before, you can issue the command `svn update` in that directory.

Handins to Autolab will be done via svn. The glue between svn and Autolab is still in the works; a lab writeup with more detail in this section will be released when everything is ironed out.
Uploading tar Archives

Until svn/Autolab integration works, you will be able to hand in your tests and code by uploading tar archives from the Autolab server. We expect Autolab to be operational well before you need to hand anything in, so this should not be necessary. However, in the event of emergency:

For the test cases, bundle the directory tests as a tar file tests.tar with

```
% tar -cvf tests.tar tests/
```

to be submitted via the Autolab server.

For the compiler, bundle the directory compiler as a tar file compiler.tar. In order to keep the files you hand in to a reasonable size, please clean up the directory and then bundle it as a tar file. For example:

```
% cd compiler
% make clean
% cd ..
% tar -cvf compiler.tar --exclude .svn compiler/
```

to be submitted via the Autolab server. Please do not include any compiled files or binaries in your hand-in file!

What to Turn In

You may turn in code and have it autograded as many times as you like, without penalty. In fact, we encourage you to hand in to verify that the Autolab grader agrees with the driver results that you use for development, and also as insurance against a last-minute rush. The last hand-in will count.

Hand in on the Autolab server:

- At least 6 test cases, two of which successfully compute a result, two of which raise a runtime exception, and two of which generate an error. The directory tests/ should only contain your test files and be submitted via subversion as described above. The server will test your test files and notify you if there is a discrepancy between your answer and the outcome of the reference implementation. If you feel the reference implementation is in error, please notify the instructors.

  Test cases are due **11:59pm on Tue Sep 13**.

- The complete compiler. The directory compiler/ should contain only the sources for your compiler and be submitted via subversion as described above. The Autolab server will build your compiler, run it on all extant test files, link the resulting assembly files against our runtime system (if compilation is successful), execute the binaries, and finally compare the actual with the expected results.

  Compilers are due **11:59pm on Tue Sep 20**.
6 Notes and Hints

We recommend reading lecture material on instruction selection and register allocation, and the optional textbook if you require further information. The written homework may also provide some insight into and practice with the algorithms and data structures needed for the assignment.

Register Allocation

We recommend implementing a global register allocator based on graph coloring. While this may be not be strictly necessary for such a simple source language, doing so now will save work in later projects where high-quality register allocation will be important. The recommended algorithm is based on chordal graph coloring as presented in lecture and detailed in the lecture notes. We recommend that you first implement register allocation without spilling, which would get almost full credit since few programs will need more than the registers available on the x86-64 processor.

We do not recommend that you implement register coalescing for this lab, unless you already have a complete, working, beautifully written compiler and some free time on your hands.

Code Generation

It is extremely important that register usage and calling conventions of the x86-64 architecture are strictly adhered to by your target code. Failure to do so will likely result in weird, possibly nondeterministic errors.

You can refresh your memory about x86-64 assembly and register convention using Randal Bryant and David O’Hallaron’s textbook supplement on x86-64 Machine-Level Programming available from the resources page on the course website. The Application Binary Interface (ABI) specification linked from the web page will also be important, if not now, then later in the course. Finally, the processor manual contains useful on the details of the instructions. Note that we use the GNU Assembler, which uses a different syntax than that given in the Intel manuals.

The tests will be run in the standard Linux environment on the lab machines; the produced assembly code must conform to those standards. We recommend the use of gcc -S to produce assembly files from C sources which can provide template code and assembly language examples.

Development Guidelines

- Format your code to a line width of no more than 100 characters.
- Tabs, if used at all, should format well with a width of 8. Some languages like ML do not indent very well with tabs, so we recommend against tabs altogether.
- Use variable names consistently.
- Use comments, but do not clutter the code too much where the meaning is clear from context.
- Develop techniques for unit testing, that is, testing modules individually. This helps limit the problem of nasty end-to-end bugs that are very difficult to track.
- Do not prematurely optimize. Write clear, simple code first and optimize only as necessary, when bottlenecks have been identified. Compiler speed is not a grading criterion!
- Be clear about the data structures and algorithms you want to implement before starting to write code.

- You may encounter performance problems in the course of your development. A profiler is definitely a useful tool in identifying the bottlenecks in your compiler. However, you must be careful in interpreting the information provided by the compiler. A particular pass in your compiler might be taking too long either because you inefficiently implemented it, or because it is inherently a hard problem, and a previous pass generated an unusually large input for subsequent passes.

- Do not prematurely generalize. Solve the problem at hand without looking ahead too much at future labs. Such generalizations are unlikely to simplify later coding because it is generally very difficult to anticipate what might be needed. Instead, they may make the present code harder to follow because of unmotivated pieces. We recommend that you take this chance to gain experience in incremental software development, which is quite orthogonal to modular software development.

7 Supported Programming Languages

This course does not require students to use any specific programming language to implement their compilers. However, we cannot support every programming language in existence. We have distributed starter code for Standard ML, Haskell, Scala, and Java. We strongly recommend that students who are well versed in a functional language take that option, because a language that supports algebraic datatypes and pattern matching allows for significantly more compact and readable code for programs that do a lot of symbol processing. If you would like to verify this claim, feel free to compare the volume of starter code in Java to that of the SML or Haskell code.

Students wishing to use other programming languages are encouraged to consult the starter code for other languages ahead of time and adapt the necessary starter code and build infrastructure. Please contact the course staff for any technical support.

If you wish to use a programming language that is significantly more verbose than Standard ML, we STRONGLY recommend that you find a partner in order to avoid being overwhelmed by the sheer volume of code. Sources of verbosity may include the lack of algebraic datatypes, lack of a module system, explicit memory management, poor support for parser generators, etc.

Please remember that your code will be the basis for future labs, and that you are working with a partner. This means your code must be readable. This also means that the code should be broken up along natural module boundaries. Finally, be careful in choosing your programming language, because you effectively commit to using it for the rest of the semester.
