ASSESSING THE RELEVANCE OF CASES AND PRINCIPLES USING OPERATIONALIZATION TECHNIQUES

Bruce Martin McLaren, Ph.D.

University of Pittsburgh, 1999

Current methods in interpretive case-based reasoning (CBR) aim to enable automated reasoners to evaluate, decide, and justify arguments through reference to past cases. A limitation of these methods, however, is that they do not adequately address the gap between abstract, open-textured rules and concrete facts. This limitation is important because domains that could employ interpretive CBR, such as the law and ethics, often lack authoritative intermediate rules that can bridge this gap. Experienced human reasoners, also lacking intermediate rules, nevertheless make decisions. To the extent they are recorded, over time these decisions cumulatively bridge the abstraction gap by applying a variety of structured, yet largely implicit, heuristic *operationalization techniques*, such as instantiating principles and past cases by connecting them to critical facts and arbitrating between competing principles.

In this dissertation, I describe SIROCCO (System for Intelligent Retrieval of Operationalized Cases and COdes), an interpretive CBR system that uses operationalization techniques, discuss the language used to represent and process engineering ethics cases, and report on experiments to evaluate SIROCCO's capabilities. The experiments show that a subset of SIROCCO's operationalization techniques provide significant improvement in retrieval accuracy over several competitive methods, including a full-text retrieval system and a version of SIROCCO that does not employ operationalization techniques. SIROCCO is also capable of explaining its output, something the competitor methods are incapable of. Finally, SIROCCO is one of the first CBR systems to factor temporal considerations into similarity assessment. The experiments, however, do not demonstrate that SIROCCO's temporal knowledge improves its retrieval accuracy. Possible reasons for this preliminary result are discussed, and suggestions for improving the impact of temporal knowledge are proposed.

This work is similar to Artificial Intelligence (AI) and Law research, but it pioneers research in a domain with a less-explicit model of argumentation, and it addresses a wider range of cases than predecessor AI and Law systems. This research makes a contribution to interpretive CBR by investigating the application of abstract, open-textured rules to concrete facts, by identifying and cataloging techniques for case-based analysis and retrieval, and by testing the use of a detailed, chronological representation of the narrative description of a case.

Foreword

This has been a long and arduous journey. Along the way I've gotten married, fathered two children, become a graybeard, celebrated the conclusion of four decades of life, and almost passed into the new millennium. First, I want to thank my wife and children for their support throughout the journey. My wife, Gabriele, has been very patient, much longer than she might have been. For providing the love, support, patience, and freedom to complete this effort, I dedicate the dissertation to her. Thank you, Gabriele.

My sons, Patrick and Dominik, have provided the inspiration. My hope is that one day they will be proud of their Daddy for all of the hard work represented by this dissertation. I like to fantasize that one day my efforts will inspire the two of them in the pursuit of their own goals. Even though my work often detracted from our time spent together, they never complained and seemed to understand, in their own way, that Daddy was doing something “important” up there on the third floor.

My advisor, Kevin Ashley, has provided abundant enthusiasm, mentoring, and intellectual guidance. I have learned much from Kevin. He is a wonderful writer who continually amazes me with his ability to clearly and concisely express the importance of a concept or research idea. He is also an excellent public speaker who stresses the importance of preparation and practice in presenting one's work. Finally, I would like to thank Kevin for understanding my somewhat unusual situation as a Ph.D. student with a job and family responsibilities. He was always willing to accommodate and support the necessary juggling of time and responsibilities.

Each member of my Ph.D. committee made a significant contribution to the work. Bruce Buchanan is truly an AI visionary who managed, more than once, to get me to see the “bigger picture.” Martha Pollack was a late addition to the committee but served a critical role nonetheless. Her enthusiasm was contagious, and she also helped to focus my attention on the all-important goal of actually *finishing*. Manuela Veloso, coming from a slightly different tradition of case-based reasoning, provided different and important perspectives on the work. I also want to thank Manuela for ordering some wonderful Portuguese food during ICCBR-95.

Vincent Aleven, my office-mate and *compadre* throughout the dissertation years, played a particularly important role in the development of my ideas. Vincent cheerfully (but critically) reviewed many of my conference papers, my thesis proposal, and portions of the dissertation.

Others in the Intelligent Systems Program at the University of Pittsburgh provided help along the way. Johanna Moore was very supportive and strongly encouraged me to finish the dissertation. Rich Thomason was a member of both my masters and thesis proposal committees. Steffi Brüninghaus reviewed several of my conference papers and provided valuable feedback.

I would also like to thank those who helped with knowledge engineering, the execution of the dissertation experiments, and the editing of the dissertation. Sharon Laubach, Nandita Mukhopadhyay, Bliksem Tobey, and Changwon Yoo did most of the case transcriptions for SIROCCO, my dissertation program. Elliott Evans co-designed the case-acquisition web site and contributed much of the text of Appendix B. David Allbritton provided valuable advice about the design of the experiment. Bob Jones, a statistics Ph.D. student at Carnegie Mellon University, helped design and develop the statistical model used in the experiments, and he also ran all of the nonparametric bootstrap tests. Lisa Bilecka and Jukka Keranen lent their expertise to the evaluation of SIROCCO. Roz Treger provided editorial comments for the entire dissertation.

Jeff Kaminski and Chip Bodin, managers at, respectively, the IBM Transarc Laboratory and Carnegie Group, Inc., were very flexible with my need to balance a paying job with my research. It was not easy holding down an almost full-time job throughout my dissertation years, but these two individuals helped to pave the way for me. I would also like to thank Jeff for allowing me to run the full-text retrieval methods on the Transarc hardware.

I would be remiss not to thank my parents and siblings. This is the first Ph.D. achieved by a member of my family, and it would not have been possible without their love, support, and encouragement over the years. My mother, Shirley, always encouraged my academic skills, particularly my writing. My father, Thomas, has provided a guidepost and model for my life. My sister, Beth, has always built up my confidence and challenged me to use my mind to the fullest. My other siblings, Mark and Debbie, have transformed, over the years, from blood family into personal friends. All of them provided the love.

Finally, I want to thank the Appalachian Trail. During my trek of this 2,138-mile trail from Springer Mountain, Georgia to Mount Kathadin, Maine over a six-month period in 1989, I made the fateful decision to pursue a Ph.D. In many respects, hiking the trail was similar to the pursuit of a Ph.D. One must fend off discouragement, loneliness, and fatigue to complete such a walk. So, too, with a Ph.D. One meets and befriends many fellow travelers on the trail. So, too, with a Ph.D. One feels an incredible sense of accomplishment and pride in completing such a long journey. So, too, with a Ph.D.*.

* The author was partially supported by a Mellon Fellowship. The research was sponsored by the National Science Foundation under grant number NSF-LIS 9720341, "Modeling Learning to Reason with Cases in Engineering Ethics: A Test Domain for Intelligent Assistance."
