Searching for High Scoring Paths

Weighted network G:

G might be an alignment graph, a PPI network, metabolic network, etc...

P = simple path

Weight(P) = sum of w(u,v) values along its edges

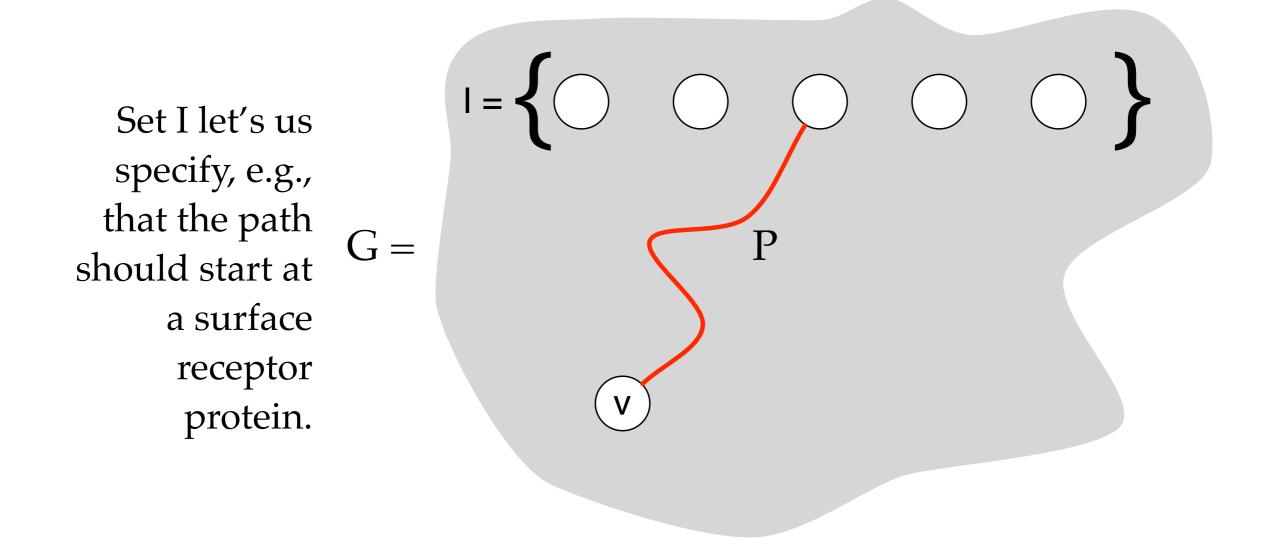

Length(P) = number of nodes in P

Goal: Low-weight, simple, length-k paths

Given: Graph G, a subset of nodes I, and a node v.

Find: The lowest-weight path P that:

- (1) starts at some vertex in I
- (2) ends at v
- (3) is of length *k* and is simple (doesn't use any vertex twice)

Given: Graph G, a subset of nodes I, and a node v.

Find: The lowest-weight, simple, length-*k* path between I and v.

Given: Graph G, a subset of nodes I, and a node v.

Find: The lowest-weight, simple, length-*k* path between I and v.

Yes. It's NP-hard. Why?

Given: Graph G, a subset of nodes I, and a node v.

Find: The lowest-weight, simple, length-*k* path between I and v.

Yes. It's NP-hard. Why?

Reduce Hamiltonian Cycle (HC) to it: To solve an HC instance $\langle G_H \rangle$, let $G = G_H$, $I = \{v\}$, and k = n.

Given: Graph G, a subset of nodes I, and a node v.

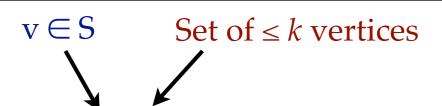

Find: The lowest-weight, simple, length-*k* path between I and v.

Yes. It's NP-hard. Why?

Reduce Hamiltonian Cycle (HC) to it: To solve an HC instance $\langle G_H \rangle$, let $G = G_H$, $I = \{v\}$, and k = n.

Without the simple condition or length-*k* condition, the problem is easy.

Dynamic Programming Algorithm

W(v, S) := minimum weight of a simple path that starts at I, visits each vertex in S, and ends at <math>v, and is of length |S|.

 $W(v, S) := \infty$ if no such path exists.

$$W(v,\{v\}) = \begin{cases} 0 & \text{if } v \in I \\ \infty & \text{if } v \notin I \end{cases}$$

$$W(v,S) = \min_{u \in S - \{v\}} W(u,S - \{v\}) + w(u,v)$$

$$\text{I=}\{\bigcirc\}$$
 Smaller size "S" set, so we can

compute $W(\bullet, \bullet)$ in order of

increasing size of S.

Ok, So:

$$OPT(I, v) = \min_{S:|S|=k} W(v, S)$$

What's the running time?

Note how "simple" this algorithm is: try all possible sets of *k* nodes, compute their optimal order, and return the best set.

Ok, So:

$$OPT(I, v) = \min_{S:|S|=k} W(v, S)$$

Note how "simple" this algorithm is: try all possible sets of *k* nodes, compute their optimal order, and return the best set.

What's the running time?

Number of sets we will consider =
$$\sum_{i=0}^{k} \binom{n}{i} = n^k$$
 all possible subsets of nodes of
$$\sum_{i=0}^{k} \binom{n}{i} = n^k$$
 size $\leq k = 1$

For each set, computing the min takes at most O(k) steps.

Therefore: Running time = $O(kn^k)$.

Color Coding

• $O(kn^k)$ is too slow for any interesting k.

• Can we do better?

• Idea: rather than keeping track of all of S, we'll keep track of less information about which nodes we've already visited.

• This will introduce a problem: we may miss the optimum path...

Color Coding

Main Step: Randomly color each node with a color from $\{1,2,...,k\}$. Let c(u) be the color of node u.

Define: a path is "colorful" if it contains exactly 1 vertex of each color.

Note: any colorful path is simple.

So, we consider this modified problem:

Given: Graph G, a subset of nodes I, and a node v.

Find: The lowest-weight, colorful, length-*k* path between I and *v*.

Color Coding DP Algorithm

 $\overline{W}(v, C) := \min weight of a path that starts at I,$ visits a vertex of <u>each color</u> in C, ends at v, and is of length |C|.

 $\overline{W}(v, C) := \infty$ if no such path exists.

$$\bar{W}(v,C) = \min_{u:c(u) \in C - \{c(v)\}} \bar{W}(u,C - \{c(v)\}) + w(u,v)$$

Intuition for faster run time: we must consider only 2^k possible sets "C" instead of $O(n^k)$

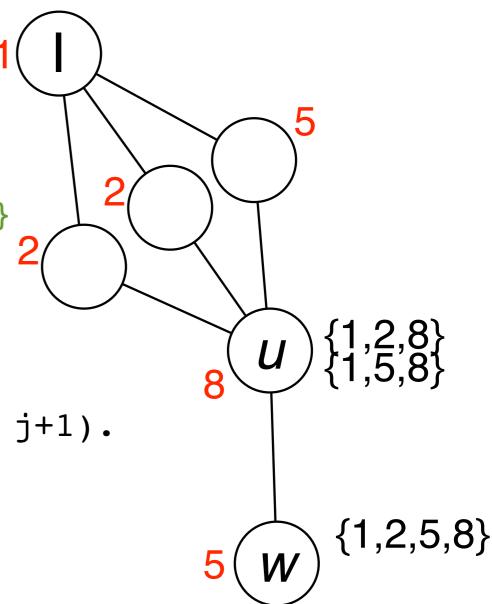

"C" keeps track of the remaining allowed colors.

$$\sum_{i=0}^{k} \binom{k}{i} = 2^k$$

Alternative View of Color Coding Algorithm

Let I be the given starting node set Let colorings(u, j) be the set of valid path colorings for a path of length j-1 from I to u

```
For all u in I: colorings(u,1) = {c(u)}
For j = 1, ..., k:
  For every edge (u, w):
    For every C in colorings(u, j):
        If c(w) not in C:
        Add C U {c(w)} to colorings(w, j+1).
```

Alternative View of Color Coding Algorithm

Let I be the given starting node set Let colorings(u, j) be the set of valid path colorings for a path of length j-1 from I to u

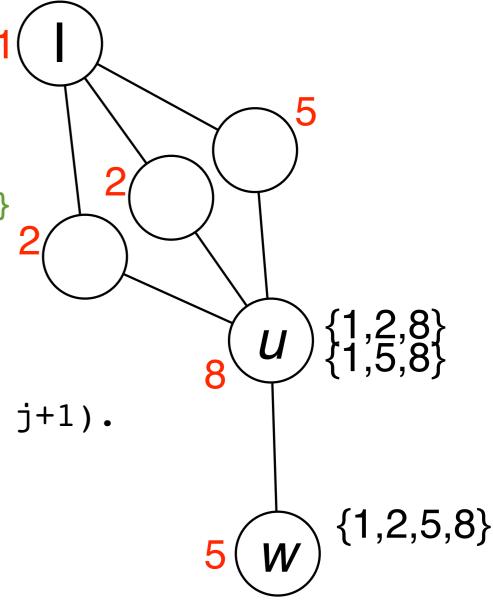

```
For all u in I: colorings(u,1) = {c(u)}
For j = 1, ..., k:

For every edge (u, w):

Of the colorings of the coloring of
```

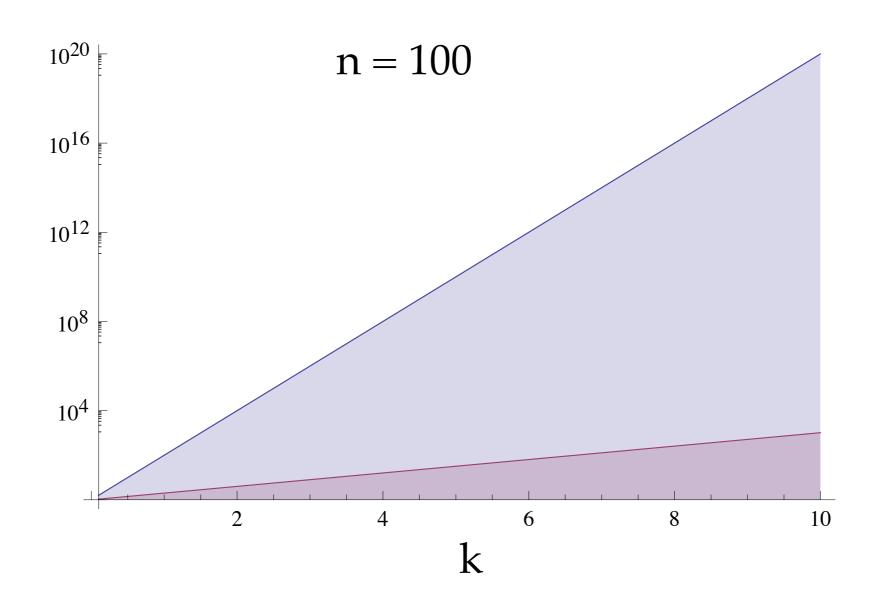

Running time:

$$\sum_{j=0}^{k} \left[\frac{|E| \binom{k}{j} j}{j} \right] = O(2^k k |E|)$$

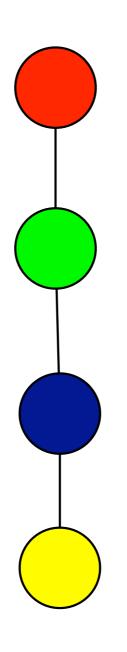

So:

We had an algorithm that was $\approx O(n^k)$ We converted it into an $\approx O(2^k)$ algorithm, but with an ϵ probability we'll miss the optimal answer.

What if the optimal path is not colorful?

Have to repeat this procedure enough times so that the probability that that happens is low.

What if the optimal path is not colorful?

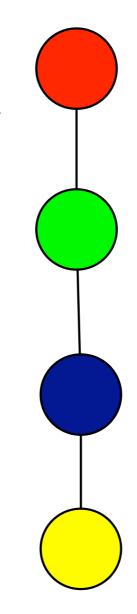

Have to repeat this procedure enough times so that the probability that that happens is low.

k! ways to make a path colorful.

kk ways to color a path.

 $Pr[Path is colorful] = k!/k^k \ge e^{-k}$.

 $Pr[OPT \text{ is colorful}] \ge e^{-k}$. $Pr[OPT \text{ is not colorful}] < (1-e^{-k})$

6	99.9%	100	36

Pheromone Response Pathway

Color Coding Summary

- Turned a slow, O(n^k) algorithm into a less-slow O
 (2^k) algorithm that is correct with high probability.
- Used on yeast to identify signaling pathways.
- Directly extends to finding good-scoring pathways in the alignment graph of PathBLAST.
