#### Problem: Cost effective wiring of a network

#### Problem: Cost effective wiring of a network

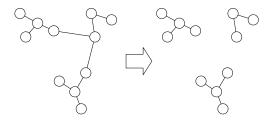

#### Other applications for the problem

1. **Circles** = DNA sequences

**Edge** u - v weighted by the similarity of sequences u and v.

Find the most parsimonious way to explain how the sequences are evolutionarily related.

2. Remove long edges  $\Rightarrow$  clustering:

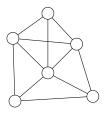

#### Graphs

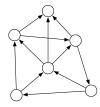

Graphs specify pairwise relationships between objects.

An undirected graph G = (V, E) is a pair of sets:

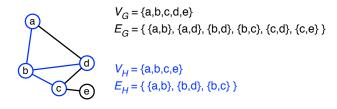

- V is a set of nodes, aka vertices.
- ▶ E is a set of two-element subsets of V. An element of E is of the form:  $e = \{u, v\}$  with  $u, v \in V$ .

A graph is directed if E is a set of ordered pairs (u, v),  $u, v \in V$ :

#### Subgraphs and components

A graph  $H = (V_H, E_H)$  is a subgraph of  $G = (V_G, E_G)$  if

- $ightharpoonup V_H \subseteq V_G$ , and
- $ightharpoonup E_H \subseteq E_G$ .

Note:  $\{u, v\} \in E_H$  implies  $u, v \in V_H$ .

Connected component: a maximal connected subgraph.

#### Graph modeling examples

#### Graphs naturally model many concepts:

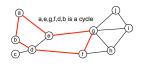

- 1. Social networks
- 2. Geographic adjacency
- 3. Polyhedra
- 4. Chemical molecules
- 5. Assigning jobs to applicants
- 6. Food webs
- 7. Finite-state machines
- 8. Markov processes
- 9. Project dependencies
- 10. World Wide Web

- 11. Telephone network
- 12. Roads
- Graphical models (e.g. Bayesian networks)
- 14. Phylogenetic relationships
- 15. Mesh approximations to surfaces

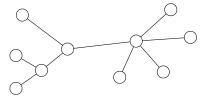

#### **Trees**

Trees are a special type of graph that occur often in algorithms.

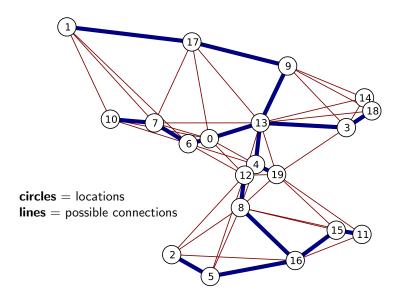

**Definition (Cycle).** A cycle of a graph G = (V, E) is a sequence of distinct vertices  $v_1, \ldots, v_k \in V$  such that  $\{v_i, v_{i+1}\} \in E$  for all  $i = 1, \ldots, k$  and  $\{v_k, v_1\} \in E$ .

**Definition** (Tree). A graph G is a tree if it is connected and contains no cycles.

#### Problem: Cost effective wiring of a network

#### The Minimum Spanning Tree problem

#### Given:

- undirected graph G with vertices for each of n objects
- weights  $d(u, v) = \text{cost of using edge } \{u, v\}.$

Find the subgraph T that connects all vertices and minimizes

$$cost(T) := \sum_{\{u,v\} \in T} d(u,v).$$

T will be a tree. Why?

#### The Minimum Spanning Tree problem

#### Given:

- undirected graph G with vertices for each of n objects
- weights  $d(u, v) = \text{cost of using edge } \{u, v\}.$

Find the subgraph T that connects all vertices and minimizes

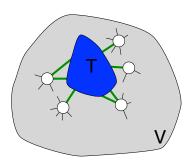

$$cost(T) := \sum_{\{u,v\} \in T} d(u,v).$$

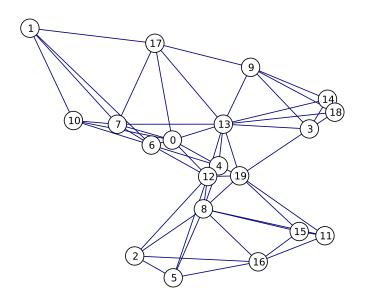

T will be a tree. Why?

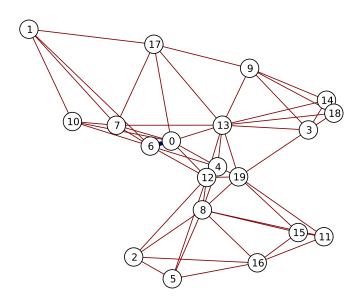

If there was a cycle, we could remove any edge on the cycle to get a new subgraph T' with smaller cost(T').

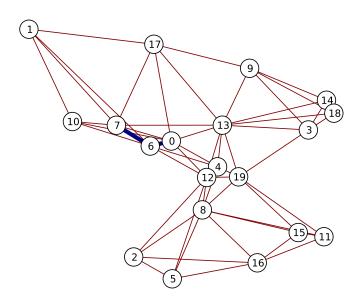

#### Prim's MST algorithm

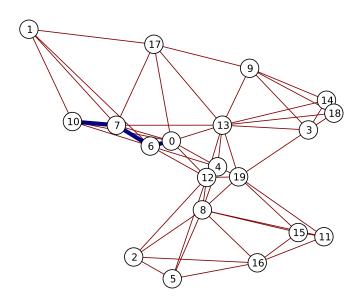

- 1. Given graph G = (V, E), select an arbitrary vertex  $s \in V$  and let T be a "tree" that contains only s.
- 2. Repeat the following |V|-1 times: Add to T the lowest-cost edge  $\{u,v\}$  where  $u\in T$  and  $v\not\in T$ .

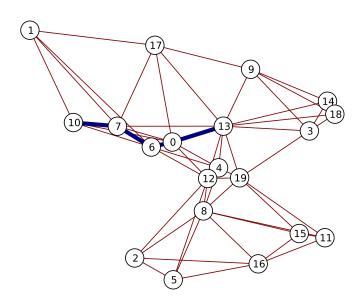

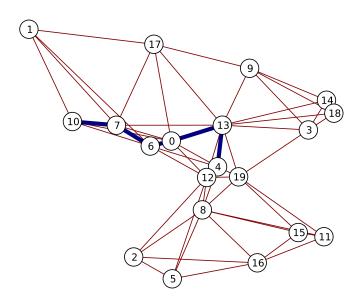

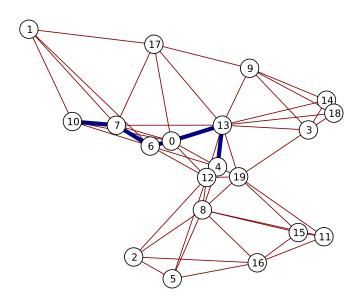

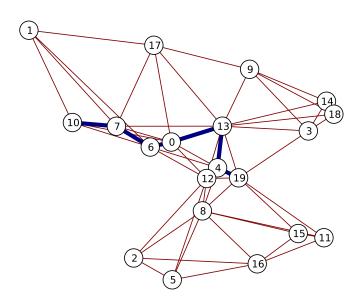

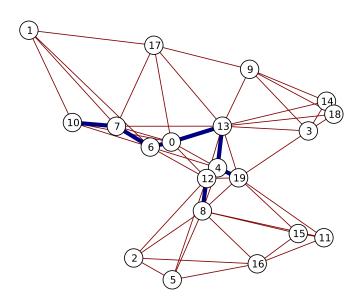

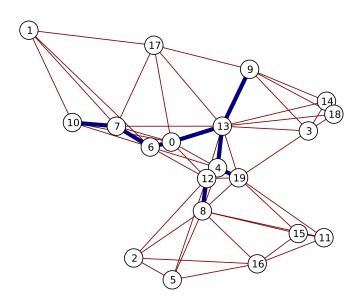

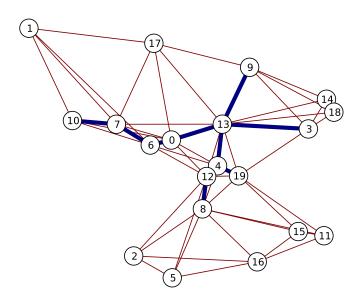

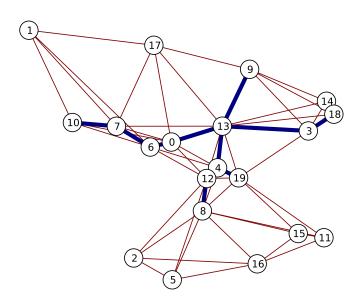

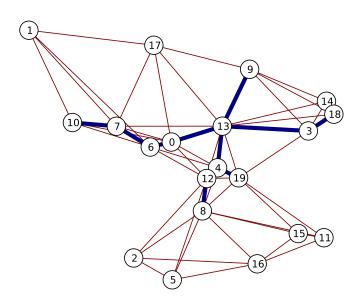

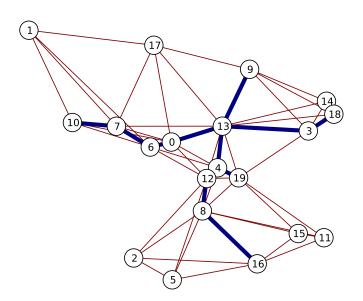

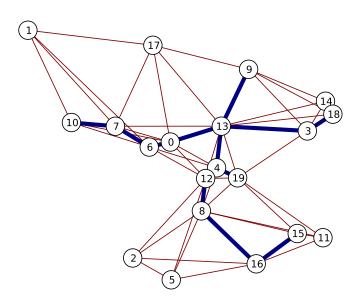

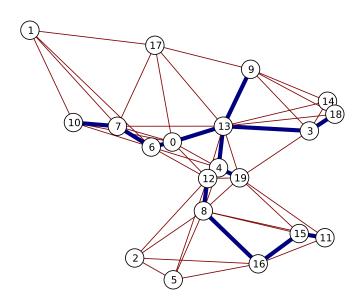

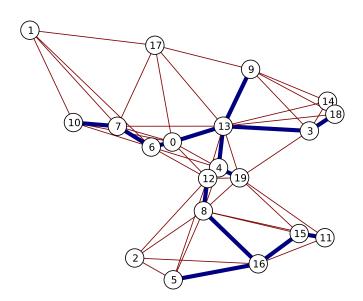

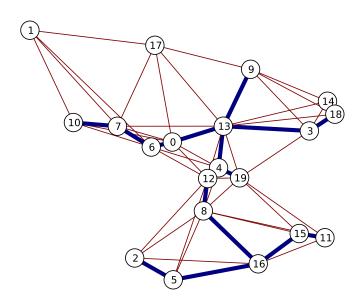

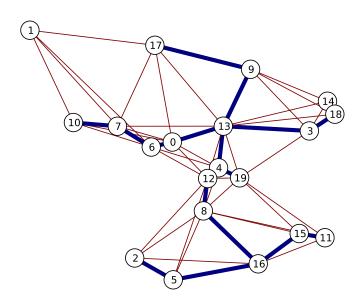

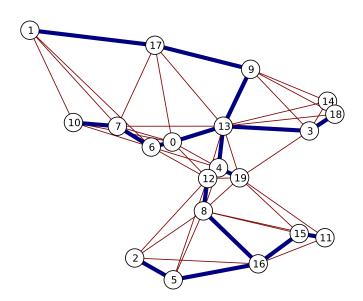

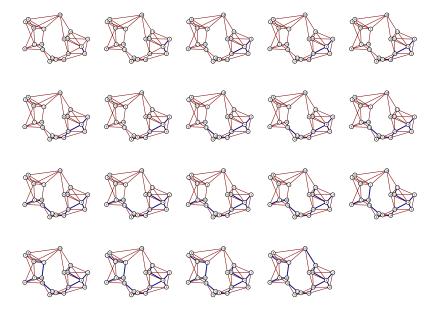

## Another example

#### Prim's MST algorithm pseudocode

```
1: # distToT[u] is distance from current tree to u
 2: for u \in V do distToT[u] \leftarrow \infty
 3: u \leftarrow s \# (s \text{ is an arbitrary start vertex})
 4: while u \neq null do
 5:
         # We put u in the tree, so distance is -\infty
        distToT[u] \leftarrow -\infty
 6:
        # Each of u's neighbors v are now incident to the current tree
 7:
        for v \in NEIGHBORS(u) do
 8:
             # If the distance is smaller than before, we have to update
 9.
             if d(u,v) < distToT[v] then
10:
                 distToT[v] \leftarrow d(u,v)
11:
                 parent[v] \leftarrow u
12:
         u \leftarrow CLOSESTVERTEX(distToT)
13:
14: return parent
```

#### Questions

- How do we know it will always find the minimum? (Correctness)
- ► How can we find quickly the CLOSESTVERTEX and iteratate ? (Choice of data structure)
- What's the longest amount of time the algorithm will take? (Worst-case running time)
- Is this the fastest possible algorithm? (Complexity theory)

# Correctness of Prim's MST Algorithm

#### **Trees**

**Theorem (Characterization of Trees).** The following statements are equivalent:

- 1. T is a tree.
- 2. T contains no cycles and n-1 edges.
- 3. T is connected and has n-1 edges.
- 4. T is connected and removing any edge disconnects it.
- 5. Any two nodes in T are connected by exactly 1 path.
- 6. T is acyclic, and adding any new edge creates exactly one cycle.

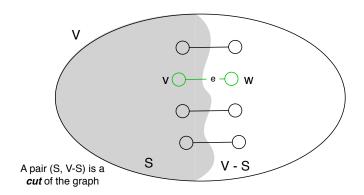

#### Assumption

We assume no two edges in G have the same edge cost.

If this doesn't hold true, we can add a very small value  $\epsilon_e$  to the weight of every edge e.

#### **Cut Property**

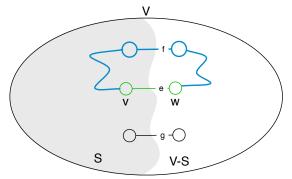

**Theorem (MST Cut Property).** Let S be a subset of nodes, with  $|S| \ge 1$  and |S| < n. Every MST contains the edge  $e = \{v, w\}$  with  $v \in S$  and  $w \in V - S$  that has minimum weight.

#### Cut Property, Proof

Suppose T doesn't contain e. Because T is connected, it must contain a path P between v and w. P must contain some edge f that "crosses the cut."

The subgraph  $T' = T - f \cup e$  has lower weight than T. T' is acyclic because the only cycle in  $T' \cup f$  is eliminated by removing f.

#### Correctness

**Theorem (Prim's correctness).** At termination, Prim's algorithm returns a subgraph T that is a minimum spanning tree.

Proof. At any point,  $T = (V_T, E_T)$  is a subgraph that is a tree.

T grows by 1 vertex and 1 edge after each iteration, so it will stop after  $|V_G|-1$  iterations and at that point T will be a spanning tree.

The pair  $(V_T, V_G - V_T)$  is a cut of G.

By the cut property, the MST contains the lowest cost edge crossing this cut.

This is exactly the edge Prim's adds to T. So, Prim's only adds edges that are in the MST.
