Texture and other Mappings

Shadows
Texture Mapping
Bump Mapping
Displacement Mapping
Environment Mapping

Angel Chapter 7

COMPUTER GRAPHICS 15-462
Announcements

• Written assignment #1 back later next week.
Shadows occur where objects are hidden from a light source
• Omit any intensity contribution from hidden light sources
• Umbra and penumbra (function of size of light source)
• Soft shadows and hard shadows (point light source at a distance)
• Important perceptual clue for connecting objects to ground (feet in particular)
• But object-to-object shadows also important
• In general, shadows from many light sources
Planar Projection Shadows

Simplest case:
Point light source (no penumbra) and shadows only on the ground plane
Good for flight simulators

Shadow is projection of polygon onto the surface with the center of projection at the light source
Planar Projection Shadows

Put light source at origin with $T(-x_1, -y_1, -z_1)$
Simple perspective projection through the origin:

$$M = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1/ y_1 & 0 & 0 \end{bmatrix}$$

Translate back with $T(x_1, y_1, z_1)$
Planar Projection Shadows in OpenGL

GlFloat m[16]; /* shadow projection matrix */
For (i=0; i<15; i++) m[i]=0.0;
m[0] = m[5] = m[10] = 1.0; m[7] = -1.0/y1;
glBegin(GL_POLYGON);
/* draw the polygon normally */
glEnd();
glMatrixMode(GL_MODELVIEW);
glPushMatrix(); /* save state*/
glTranslatef(x1,y1,z1); /* translate back */
glMultMatrixf(m); /* project*/
glTranslatef(-x1,-y1,-z1); /* move light to origin */
glColor3fv(shadow_color);
glBegin(GL_POLYGON);
/* draw the polygon again */
glEnd();
glPopMatrix(); /* restore state */
Question

• If a perspective transform does a point light source, what does a directional light source?

• [Angel demo]
Limitations of Planar Projection Shadows

• Only do shadows on flat surfaces
• Objects must be far enough apart to not cast shadows on each other—although artifacts often hard to detect.

• Related approach: projective textures
  (Blurred drop shadow texture from video game “Halo”)

Computer Graphics 15-462
Other Shadow Algorithms

Shadow Maps (Williams, 1978):

- Z-Buffer algorithm
- Works for curved surfaces

1. Render from light source to compute depth map (z distance to closest object for each pixel in the map).
2. While rendering, if a point \((x,y,z)\) is visible, map \((x,y,z)\) in the coordinates of the viewpoint to \((x',y',z')\), the coordinates of the point from the light.
3. If \(z'\) is greater than the value in the z-buffer for that point, then a surface is nearer to the light source than the point under consideration and the point is in shadow. If so, render with a shadow intensity, if not render as normal.

- Handles multiple light sources (with multiple z-buffers), moving objects and lights (at the cost of several renderings). Clearly a winning strategy with hardware.
Shadow Maps (Williams, 1978)
Other Shadow Algorithms

Projecting polygons—scan line (Appel 1968)
Build a data structure that links all polygons where one might shadow the other (depends on polygon location and lighting source location—animation would require recalculating). Multiple data structures for multiple lights.

When scan converting have three possibilities
- Shadow polygon does not cover generated scan line segment
- Shadow polygon completely covers segment (adjust intensity for shadow)
- Shadow polygon partially covers segment, subdivide and repeat
Other Shadow Algorithms

Shadow Volumes (Crow 1977)
Compute the volume of space swept out by an object, intersected with the viewing volume.

Include these invisible objects in rendering pipeline. Render visible objects as in shadow if they are in front of a back facing shadow polygon and in back of a front facing polygon. Extend the z buffer to contain this extra information.
Examples: Shadow Volumes

Figure 6.46. Left: The lines from a point light are extended through the vertices of a triangle to form an infinite pyramid. Right: The upper part is a pyramid, and the lower part is an infinite truncated pyramid, also called the shadow volume. All geometry that is inside the shadow volume is in shadow.
Texture Mapping
Last time we talked about shading. But uniformly colored or shaded surfaces are unrealistic.

- Real objects have small surface features
- One option: use a huge number of polygons with appropriate surface coloring and reflectance characteristics
- Another option: use a mapping algorithm to modify the shading algorithm
  - Texture mapping
  - Bump mapping
  - Displacement mapping
  - Environmental mapping
The Quest for Visual Realism

At what point do things start looking real?

Model

Model + Shading

Model + Shading + Textures

2D Texture Mapping

Texture images to make our surfaces more life-like
- Scan textures from the world (clouds, wood grain) or paint them yourself
- Store the texture in a 2D image
- Map the image onto the surface by a function which maps \((u,v)\) coordinates of our parametric surface onto \((x,y)\) image coordinates
- When shading a surface point, we look up the appropriate pixel from the 2D image, and use that to affect the final color

Voila! Your favorite picture painted onto a donut. This technique is called *parametric texture mapping*

But how to map from texture coordinates to object coordinates? Easy for a parametric surface, less obvious for other models.
Texture Mapping: General

Texture Space  Object Space  Screen Space

\[ T(u) \]

\[ T(u, v) \]

\[ T(u, v, w) \]

\( (x_w, y_w, z_w) \rightarrow (x_s, y_s) \)
Specifying the Mapping Function

Some objects have natural parameterizations:

- Sphere: use spherical coordinates \((\phi, \theta) = (2\pi u, \pi v)\)
- Cylinder: use cylindrical coordinates \((u, \theta) = (u, 2\pi v)\)
Specifying the Mapping Function

Some objects have natural parameterizations:
- Parametric surface (such as B-spline or Bezier): use patch parameters \((u,v)\)

\[
\begin{align*}
  u &= u_{\text{min}} + \frac{s - s_{\text{min}}}{s_{\text{max}} - s_{\text{min}}} (u_{\text{max}} - u_{\text{min}}) \\
v &= v_{\text{min}} + \frac{t - t_{\text{min}}}{t_{\text{max}} - t_{\text{min}}} (v_{\text{max}} - v_{\text{min}})
\end{align*}
\]

Doesn’t take into account the curvature of the surface: stretching. Just like with roller coaster.
Specifying the Mapping Function

What about arbitrary polygonal objects?

Two step mapping:

- To a canonical shape first
- Then project normals from object

a) From texture value to object
b) Use normals to find texture
c) Line from center to point to texture value
Or design the mapping by hand

For each triangle in the model establish a corresponding region in the phototexture

During rasterization interpolate the coordinate indices into the texture map
Demo: “uvMapper”

Texture Mapping in OpenGL

A parallel pipeline for pixel operations: Texture mapping is part of the shading process
Texture Mapping in OpenGL

Glubyte my_texels[512][512];
glTexImage2D(GL_TEXTURE_2D, 0, 3, 512, 512, 0,
           GL_RGB, GL_UNSIGNED_BYTE, my_texels);
/* level, components, w, h, border, format, type, tarray */

glEnable(GL_TEXTURE_2D);

/* assign texture coordinates */
 glBegin(GL_QUAD);
  glTexCoord2f(0.0, 0.0); glVertex2f(x1,y1,z1);
  glTexCoord2f(1.0, 0.0); glVertex2f(x2,y2,z2);
  glTexCoord2f(1.0,1.0); glVertex2f(x3,y3,z3);
  glTexCoord2f(0.0,1.0); glVertex2f(x4,y4,z4);
 glEnd();
Grungy details we’ve ignored

• Specify s or t out of range? Use `GL_TEXTURE_WRAP` in `glTexParameteri` because many textures are carefully designed to repeat

• Aliasing? Mapping doesn’t send you to the center of a texel. Can average nearest 2x2 texels using `GL_LINEAR`

• Mipmapping: use textures of varying resolutions. 64x64 becomes 32x32, 16x16, 8x8, 4x4, 2x2 and 1x1 arrays with `gluBuild2Dmipmaps`
What is aliasing?

• Sampling error when mapping texture images to screen
What is aliasing?

- An on-screen pixel may not map neatly to a texel.
Example: Checkerboard

• Particularly severe problems in regular textures
The Beginnings of a Solution: Mipmapping

- Pre-calculate how the texture should look at various distances, then use the appropriate texture at each distance. This is called *mipmapping*.
- “Mip” → “multum in parvo” or “many things in a small place”
- Each mipmap (each image below) represents a level of resolution.
- Powers of 2 make things much easier.
The Beginnings of a Solution

- Problem: Clear divisions between different depth levels
- Mipmapping alone is unsatisfactory.
Another Component: Filtering

• Take the average of multiple texels to obtain the final RGB value
• Typically used along with mipmapping
• *Bilinear filtering*
  – Average the four surrounding texels
  – Cheap, and eliminates some aliasing, but does not help with visible LOD divisions

(demonstration movies)
Another Component: Filtering

- **Trilinear filtering**
  - Interpolate between two LODs
  - Final RGB value is between the result of a bilinear filter at one LOD and a second bilinear filter at the next LOD
  - Eliminates “seams” between LODs
  - At least twice as expensive as bilinear filtering
Another Component: Filtering

• **Anisotropic filtering**
  – Basic filtering methods assume that a pixel on-screen maps to a square (isotropic) region of the texture
  – For surfaces tilted away from the viewer, this is not the case!

Figure 5. Anisotropic footprints are very common.

Image courtesy of nVidia
Another Component: Filtering

• *Anisotropic filtering*
  – A pixel may map to a rectangular or trapezoidal section of texels—shape filters accordingly and use either bilinear or trilinear filtering
  – Complicated, but produces very nice results

Texture Generation

Photographs
Drawings
Procedural methods (2D or 3D)
Associate each x,y,z value directly with an s,t,r value in the texture block (sculpting in marble and granite)
Procedural Methods

Reaction-Diffusion
Greg Turk, Siggraph ‘91
Solid Textures

- Have a 3-D array of texture values (e.g., a block of marble)
  - Use a function \([\text{xyz}] \rightarrow [\text{RGB}]\) to map colors to points in space
- Such a 3D map is called a solid texture map
- In practice the map is often defined procedurally
  - No need to store an entire 3D array of colors
  - Just define a function to generate a color for each 3D point
- The most interesting solid textures are random ones
  - A great marble algorithm has now become cliché
- Evaluate the texture coordinates in object coordinates - otherwise moving the object changes its texture!

From: *An Image Synthesizer* by Ken Perlin, SIGGRAPH '85
Uses for Texture Mapping (Heckbert 1986)

Use texture to affect a variety of parameters

- surface color (Catmull 1974)
- surface reflectance
- normal vector
- geometry
- transparency
- light source radiance

- color (radiance) of each point on surface
- reflectance coefficients $k_d$, $k_s$, or $n_{shiny}$
- bump mapping (Blinn 1978)
- displacement mapping
- transparency mapping (clouds) (Gardener 1985)
- environment mapping (Blinn 1978)
Radiance vs. Reflectance Mapping

Texture specifies (isotropic) radiance for each point on surface

Texture specifies diffuse color ($k_d$ coefficients) for each point on surface - three coefficients, one each for R, G, and B radiance channels
Multitexturing

Figure 9-13  Multitexture Processing Pipeline

(See RedBook p.422 for details)
Bump Mapping: A Dirty Trick

• Which spots bulge out, and which are indented?

• Answer: None! This is a flat image.

• The human visual system is hard-coded to expect light from above.

• In CG, we can perturb the normal vector without having to make any actual change to the shape.
Bump Mapping

• Basic texture mapping paints on to a smooth surface
• How do you make a surface look *rough*?
  – Option 1: model the surface with many small polygons
  – Option 2: perturb the normal vectors before the shading calculation

![Real Bump](image1)
![Fake Bump](image2)
![Flat Plane](image3)

Sphere w/Diffuse Texture Map + Bump Map = Sphere w/Diffuse Texture + Bump Map
Bump Mapping

- Basic texture mapping paints on to a smooth surface
- How do you make a surface look *rough*?
  - Option 1: model the surface with many small polygons
  - Option 2: perturb the normal vectors before the shading calculation
    - the surface doesn’t actually change, but shading makes it look that way
    - bump map fakes small displacements above or below the true surface
    - can use texture-mapping for this
      - texture image gives amount to perturb surface normal

What kind of anomaly will this produce?

Greg Turk
Bump Mapping

Let \( p(u, v) \) be a point on a parametric surface. Unit normal is

\[
\mathbf{n} = \frac{\mathbf{p}_u \times \mathbf{p}_v}{|\mathbf{p}_u \times \mathbf{p}_v|}
\]

Where

\[
\mathbf{p}_u = \begin{bmatrix}
\frac{\partial x}{\partial u} \\
\frac{\partial y}{\partial u} \\
\frac{\partial z}{\partial u}
\end{bmatrix} \quad \mathbf{p}_v = \begin{bmatrix}
\frac{\partial x}{\partial v} \\
\frac{\partial y}{\partial v} \\
\frac{\partial z}{\partial v}
\end{bmatrix}
\]

are partial derivative vectors tangent to the surface at point \( P \).
Bump Mapping

Displace the surface in the normal direction by \( d(u, v) \)

Then \( \mathbf{p}' = \mathbf{p} + d(u, v) \mathbf{n} \)

We don’t actually change the surface \((\mathbf{p})\), just the normal. Need to calculate:

\[
\mathbf{n}' = \mathbf{p}_u' \times \mathbf{p}_v'
\]
Bump Mapping

Compute the partial derivatives by differentiating \( p' \)

\[
\begin{align*}
p'_u &= p_u + \frac{\partial d}{\partial u} n + d(u, v)n_u \\
p'_v &= p_v + \frac{\partial d}{\partial v} n + d(u, v)n_v
\end{align*}
\]

If \( d \) is small

\[
n' = n + \frac{\partial d}{\partial v} n \times p_v + \frac{\partial d}{\partial u} n \times p_u
\]

Pre-compute arrays of \( \frac{\partial d}{\partial v}, \frac{\partial d}{\partial u} \)
Bump Mapping

• We can perturb the normal vector without having to make any actual change to the shape.
• This illusion can be seen through—how?

Original model (5M)  Simplified (500)  Simple model with bump map
Another Bump Mapping Example

Cylinder w/Diffuse Texture Map

Bump Map

+ =
Displacement Mapping

- Use texture map to displace each point on the surface
  - Texture value gives amount to move in direction normal to surface

- How is this different from bump mapping?
Environment Mapping

Specular reflections that mirror the environment
Environment Mapping

Specular reflections that mirror the environment

Cube is a natural intermediate object for a room
Environment Mapping

- Generate the environment map either by scanning or by rendering the scene from the point of view of the object (win here because people’s ability to do the reverse mapping in their heads is bad—they won’t notice flaws)
- OpenGL can automatically generate the coordinates for a spherical mapping. Given a vertex and a normal, find point on sphere that has same tangent:

```c
glTexCoordfv(GL_S, GL_SPHERE_MAP, 0);
glTexCoordfv(GL_T, GL_SPHERE_MAP, 0);
glEnable (GL_TEXTURE_GEN_S);
glEnable (GL_TEXTURE_GEN_T);
```
Environment Mapping: Cube Maps
More Tricks: Light Mapping

- *Quake* uses *light maps* in addition to (radiance) texture maps. Texture maps are used to add detail to surfaces, and light maps are used to store pre-computed illumination. The two are multiplied together at run-time, and cached for efficiency.
