

Lecture 9: Symbolic Model Checking

- Basic CTL Fixpoint Theorems
- Ordered Binary Decision Diagrams (BDDs)
- Representing Transition Systems with BDDs
- Symbolic Model Checking Algorithm

Breakthrough: Symbolic Model Checking

Method used by most “**industrial strength**” model checkers:

- uses **boolean encoding** for state machine and sets of states.
- can handle much larger designs – **hundreds of state variables**.
- **BDDs** traditionally used to represent boolean functions.

Symbolic Model Checking with BDDs

Ken McMillan implemented a version of the CTL model checking algorithm using **Binary Decision Diagrams** in 1987.

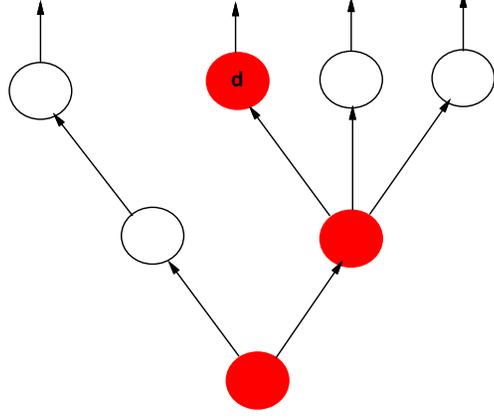

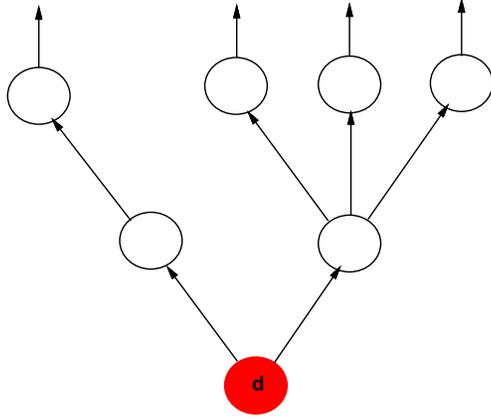

Carl Pixley at Motorola independently developed a similar algorithm, as did the French researchers, Coudert and Madre.

BDDs enabled handling much larger concurrent systems. (usually, an **order of magnitude increase** in hardware latches!)

Fixpoint Algorithms

$$EF\ d = d \wedge EX\ EF\ d$$

Fixpoint Algorithms (cont.)

Key properties of $\mathbf{EF} p$:

1. $\mathbf{EF} p = d \wedge \mathbf{EX} \mathbf{EF} p$

2. $U = d \wedge \mathbf{EX} U$ implies $\mathbf{EF} p \subseteq U$

We write $\mathbf{EF} p = \mathbf{Lfp} U.p \wedge \mathbf{EX} U$.

How to compute $\mathbf{EF} p$:

$$U_0 = \mathbf{False}$$

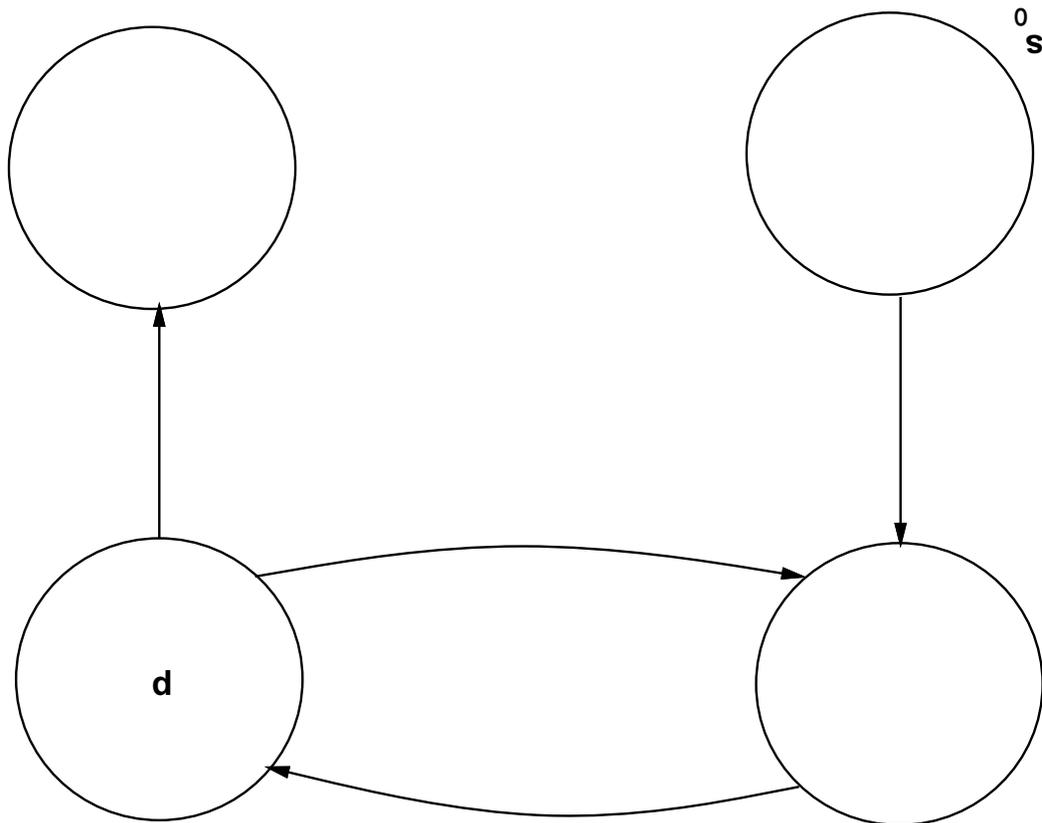

$$U_1 = d \wedge \mathbf{EX} U_0$$

$$U_2 = d \wedge \mathbf{EX} U_1$$

$$U_3 = d \wedge \mathbf{EX} U_2$$

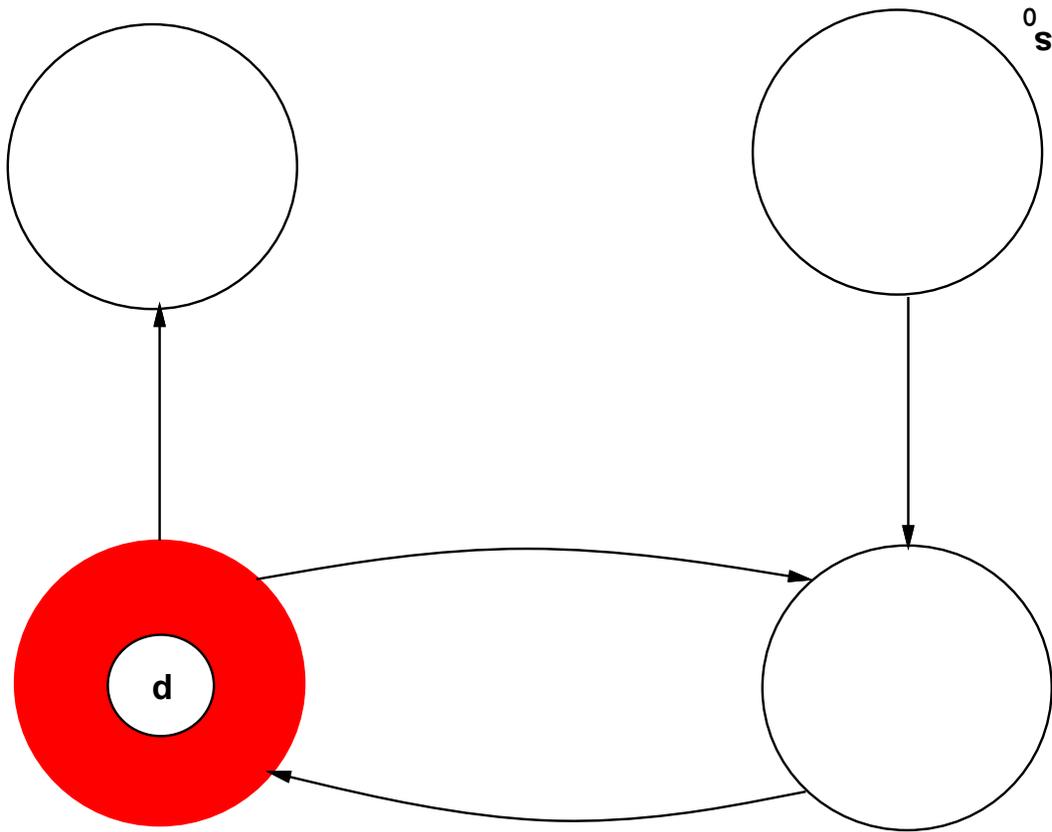

⋮

$$\emptyset = {}^0\Omega$$

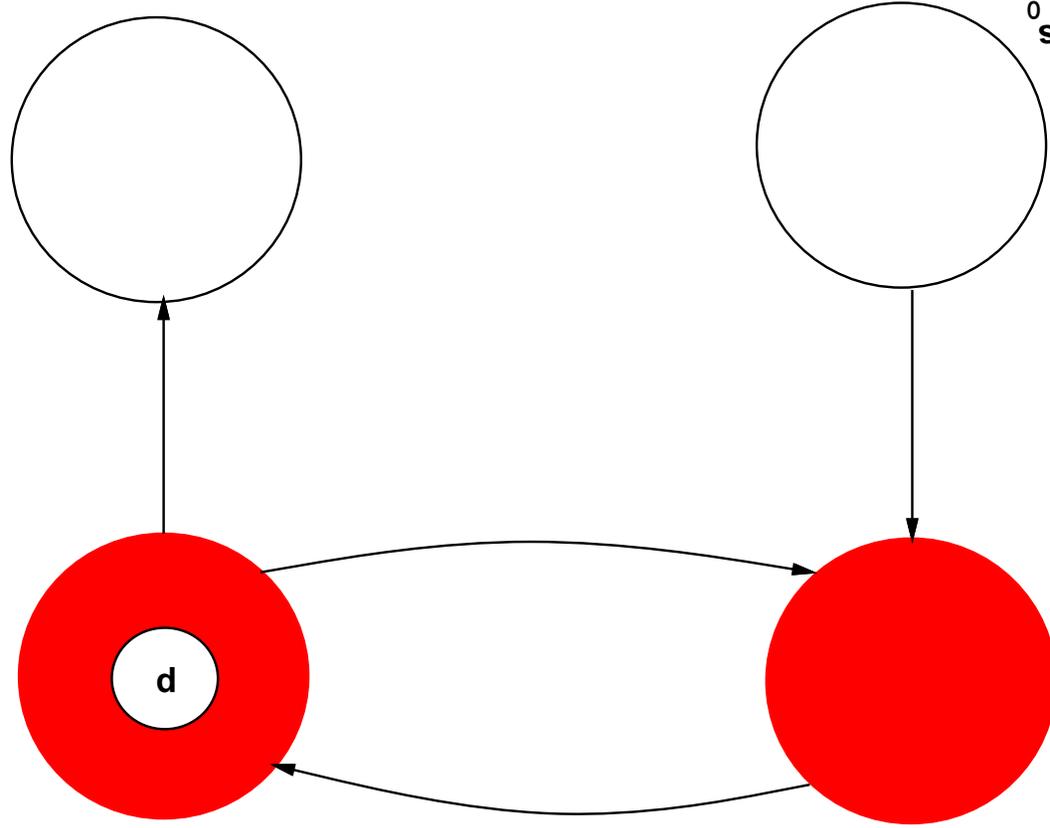

$$M, s_0 \models \text{EF } d?$$

$$U_1 = p \vee \mathbf{EX} U_0$$

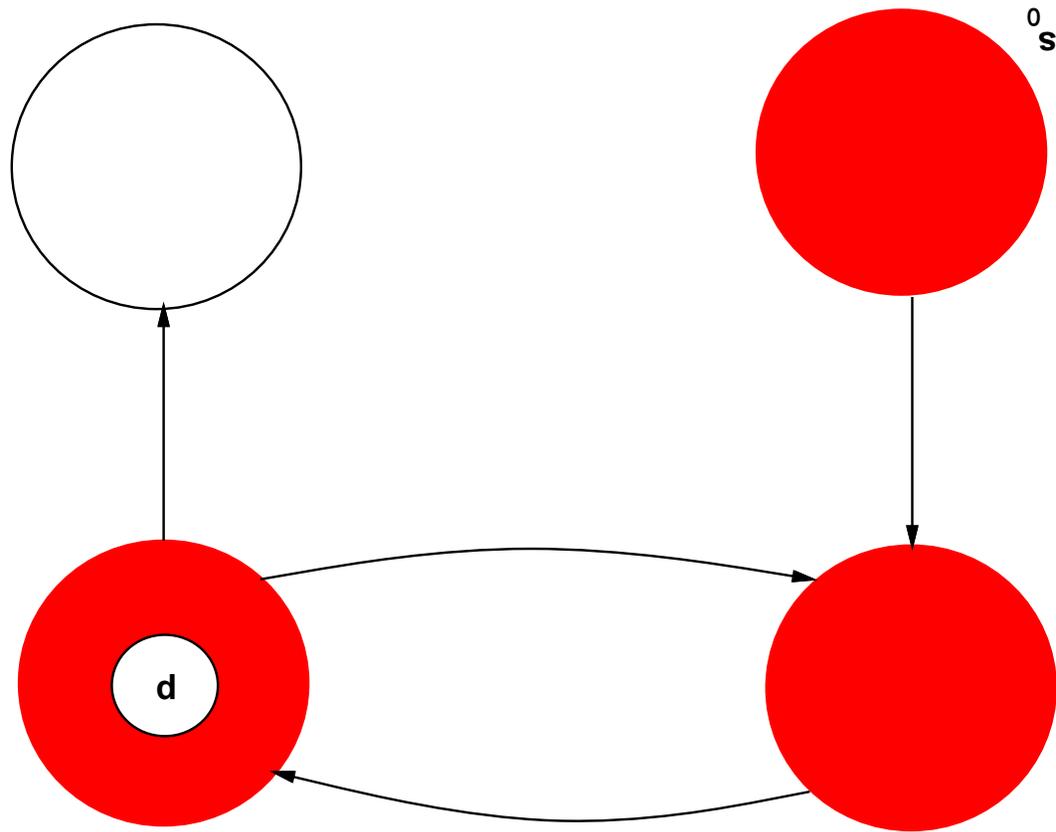

$$M, s_0 \models \mathbf{EF} p?$$

$$U_2 = p \vee \text{EX } U_1$$

$$M, s_0 \models \text{EF } p?$$

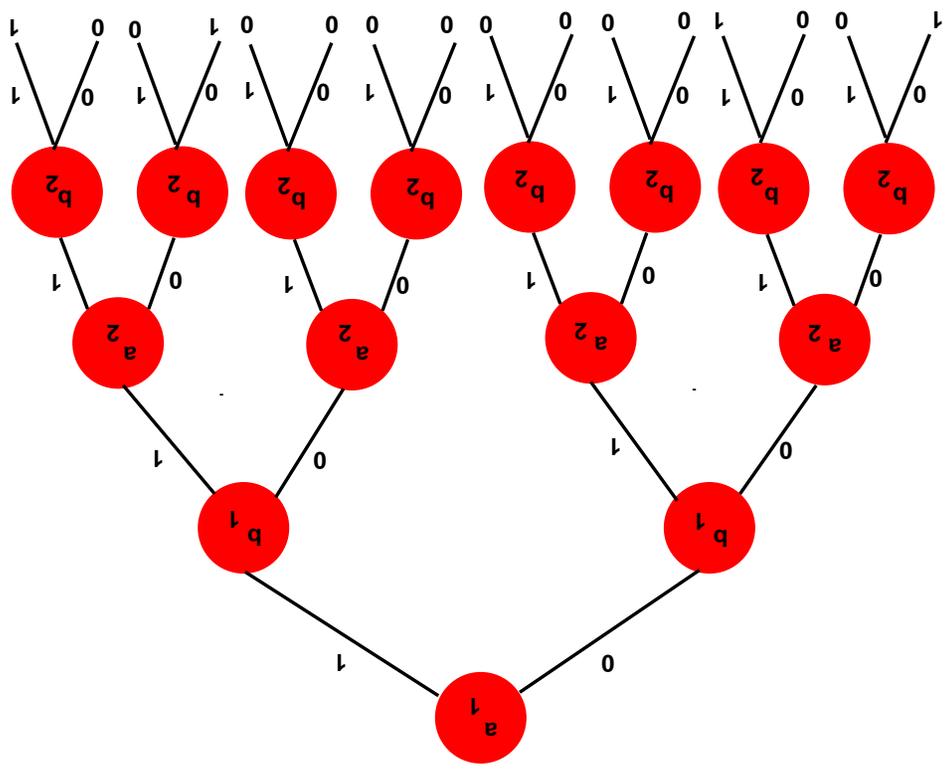

$$U_3 = p \vee \mathbf{EX} U_2$$

$$M, s_0 \models \mathbf{EF} p?$$

Ordered Binary Decision Trees and Diagrams

Ordered Binary Decision Tree for the two-bit comparator, given by the formula $f(a_1, a_2, b_1, b_2) = (a_1 \leftrightarrow b_1) \wedge (a_2 \leftrightarrow b_2)$, is shown in the figure below:

From Binary Decision Trees to Diagrams

An **Ordered Binary Decision Diagram (OBDD)** is an ordered decision tree where

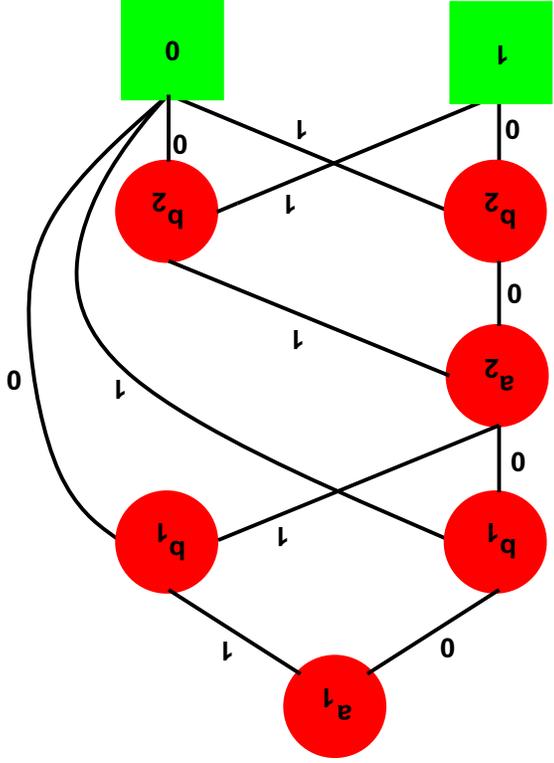

- All isomorphic subtrees are combined, and
- All nodes with isomorphic children are eliminated.

Given a parameter ordering, **OBDD** is unique up to isomorphism.

- R. E. Bryant. Graph-based algorithms for boolean function manipulation. *IEEE Transactions on Computers*, C-35(8):677–691, 1986.

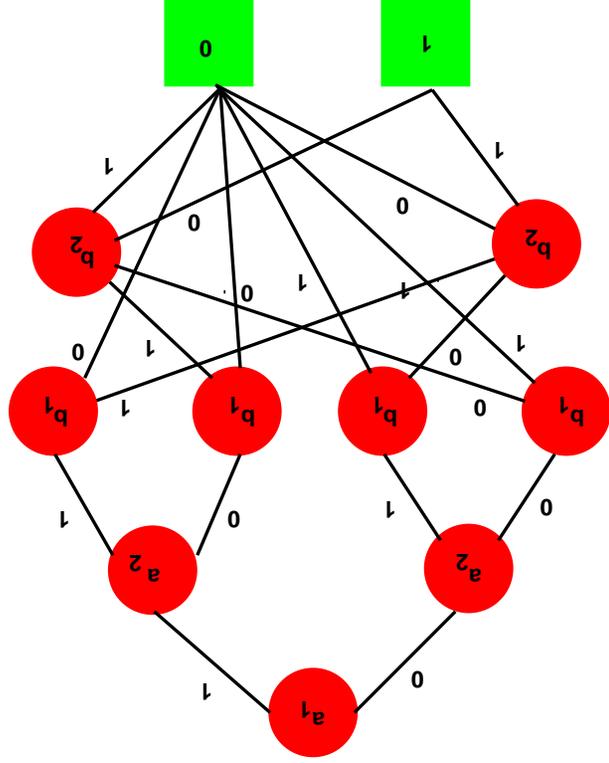

OBDD for Comparator Example

If we use the ordering $a_1 < b_1 < a_2 < b_2$ for the comparator function, we obtain the OBDD below:

Variable Ordering Problem

If we use the ordering $a_1 < a_2 < b_1 < b_2$ for the comparator function, we get the OBDD below:

Variable Ordering Problem (Cont.)

For an n -bit comparator:

- if we use the ordering $a_1 < b_1 < \dots < a_n < b_n$, the number of vertices will be $3n + 2$.
- if we use the ordering $a_1 > \dots > a_n > b_1 > \dots > b_n$, the number of vertices is $3 \cdot 2^n - 1$.

Moreover, there are boolean functions that have exponential size OBDDs for any variable ordering.

An example is the middle output (n^{th} output) of a combinational circuit to multiply two n bit integers.

Logical operations on OBDD's

- Logical negation: $\neg f(a, b, c, d)$

Replace each leaf by its negation

- Logical conjunction: $f(a, b, c, d) \wedge g(a, b, c, d)$

– Use Shannon's expansion as follows,

$$f \cdot g = \bar{a} \cdot (f|\bar{a} \cdot g|\bar{a}) + a \cdot (f|a \cdot g|a)$$

to break problem into two subproblems. Solve subproblems recursively.

– Always combine isomorphic subtrees and eliminate redundant nodes.

– Hash table stores previously computed subproblems

– Number of subproblems bounded by $|f| \cdot |g|$.

Logical operations (cont.)

- **Boolean quantification:** $\exists a : f(a, b, c, d)$

– By definition,

$$\exists a : f = f|_{\bar{a}} \vee f|_a$$

– $f(a, b, c, d)|_a$: replace all a nodes by left sub-tree.

– $f(a, b, c, d)|_{\bar{a}}$: replace all a nodes by right sub-tree.

Using the above operations, we can build up OBDD's for complex boolean functions from simpler ones.

Symbolic Model Checking Algorithm

How to represent state-transition graphs with **Ordered Binary Decision Diagrams**:

Assume that system behavior is determined by n **boolean state variables** v_1, v_2, \dots, v_n .

The Transition relation N will be given as a boolean formula in terms of the state variables:

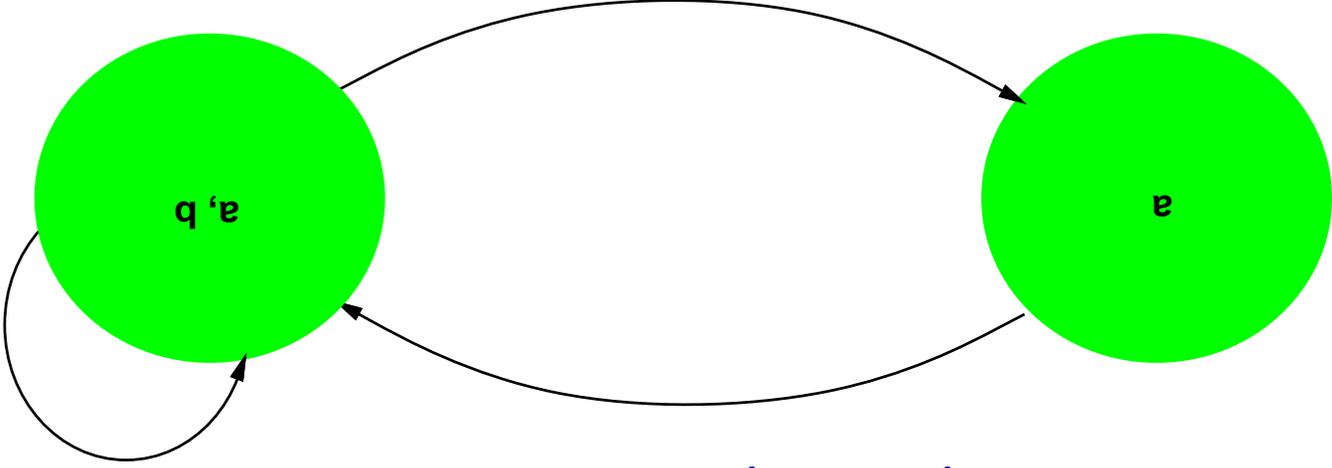

$$N(v_1, \dots, v_n, v'_1, \dots, v'_n)$$

where v_1, \dots, v_n represents the **current state** and v'_1, \dots, v'_n represents the **next state**.

Now convert N to a OBDD!!

Symbolic Model Checking (cont.)

Representing transition relations symbolically:

Boolean formula for transition relation:

$$\begin{aligned} & \vee (a \vee b \vee a' \vee \neg b') \\ & \vee (a \vee b \vee a' \vee b') \\ & (a \vee \neg b \vee a' \vee b') \end{aligned}$$

Now, represent as an OBDD!

Symbolic Model Checking (cont.)

Consider $f = \mathbf{EX} p$.

Now, introduce state variables and transition relation:

$$f(\bar{v}) = \exists \bar{v}' [N(\bar{v}, \bar{v}') \wedge p(\bar{v}')]]$$

Compute OBDD for relational product on right side of formula.

Symbolic Model Checking (cont.)

How to evaluate fixpoint formulas using OBDDs:

$$\mathbf{EF}^d p = \mathbf{Lfp} U.p \wedge \mathbf{EX} U$$

Introduce state variables:

$$\mathbf{EF}^d p = \mathbf{Lfp} U.p \wedge (\exists v' [N(v, v') \vee U(v')])$$

Now, compute the sequence

$$U^0(v), U^1(v), U^2(v), \dots$$

until convergence.

Convergence can be detected since the sets of states $U^i(v)$ are represented as OBDDs.
