Predicate Transformers

Let $M = (S, R, L)$ be an arbitrary finite Kripke structure.

$\text{Pred}(S)$ is the lattice of predicates over S . Each predicate is identified with the set of states that make it true. The ordering is set inclusion.

Thus, the least element in the lattice is the empty set, denoted by False , and the greatest element in the lattice is the set of all states, denoted by True .

A functional $F : \text{Pred}(S) \rightarrow \text{Pred}(S)$ is called a predicate transformer.

- E. M. Clarke and E. A. Emerson. Synthesis of synchronization skeletons for branching time temporal logic. In *Logic of Programs: Workshops, Yorktown Heights, NY, May 1981*, volume 131 of *Lecture Notes in Computer Science*. Springer-Verlag, 1981.

Let $\tau : \text{Pred}(S) \longrightarrow \text{Pred}(S)$ be a predicate transformer, then

1. τ is monotonic provided that $P \subseteq Q$ implies $\tau[P] \subseteq \tau[Q]$;
2. τ is \cup -continuous provided that $P_1 \subseteq P_2 \subseteq \dots$ implies $\tau[\cup_i P_i] = \cup_i \tau[P_i]$;
3. τ is \cap -continuous provided that $P_1 \supseteq P_2 \supseteq \dots$ implies $\tau[\cap_i P_i] = \cap_i \tau[P_i]$.

Monotonicity and Continuity

If τ is monotonic, then it has a least fixpoint, $\text{Lfp } Z[\tau(Z)]$, and a greatest fixpoint, $\text{gfp } Z[\tau(Z)]$.

Basic Fixpoint Theorems

- Let M be a finite Kripke structure and let τ be a monotonic predicate transformer on S .
-
1. The functional τ is both \cup -continuous and \cap -continuous.
 2. For every i , $\tau^i(\text{False}) \subseteq \tau^{i+1}(\text{False})$ and $\tau^i(\text{True}) \supseteq \tau^{i+1}(\text{True})$.
 3. There is an integer i_0 such that for every $j \geq i_0$, $\tau^j(\text{True}) = \tau^{i_0}(\text{True})$.
 4. There is an integer j_0 such that $\text{lfp } Z[\tau(Z)]$ is $\tau^{i_0}(\text{False})$.
- There is an integer j_0 such that $\text{gfp } Z[\tau(Z)]$ is $\tau^{j_0}(\text{True})$.

Some Useful Lemmas

As a consequence of the preceding lemmas, if τ is monotonic, its least fixpoint can be computed by the following program.

```

function Lfp(Tau: PredicateTransformer)
begin
  while ( $O \neq O'$ ) do
     $O' := \text{Tau}(O)$ ;
  begin
     $O := \text{False}$ ;
     $O' := O$ ;
    begin
      end;
    end;
  end;
  return( $O$ );
end;

```

Least Fixpoint Algorithm

It follows directly that $\mathcal{Q} = \text{lfp } Z[\tau(Z)]$ and that the value returned is the least fixpoint.

When the loop terminates, we have $\mathcal{Q} = \tau[\mathcal{Q}]$ and $\mathcal{Q} \subseteq \text{lfp } Z[\tau(Z)]$.

So, the number of iterations before the loop terminates is bounded by the cardinality of S .

$$\text{False} \subseteq \tau(\text{False}) \subseteq \tau^2(\text{False}) \subseteq \dots$$

Lemma 2 implies that

It is easy to see that at the beginning of the i -th iteration, $\mathcal{Q} = \tau^{i-1}(\text{False})$ and $\mathcal{Q}' = \tau^i(\text{False})$.

$$((\tau(Z) Z \text{fp } \mathcal{Q}') \vee (\mathcal{Q}' = \tau[\mathcal{Q}]))$$

The invariant for the while loop is given by the assertion

Correctness of Algorithm

```

function Gfp(Tau: PredicateTransformer)
begin
  O := True;
  while (O ≠ O') do
    O' := Tau(O);
  begin
    O := O';
    begin
      O' := Tau(O);
    end;
  end;
end;
return (O)
end;

```

The greatest fixpoint of τ may be computed in a similar manner. Essentially the same argument can be used to show that the procedure terminates and that the value it returns is $\text{Gfp } Z \left[\tau(Z) \right]$.

Greates Fixpoint Algorithm

We will only prove the characterization for \mathbf{EU} .

- $\mathbf{EG} f_1 = \mathbf{gfp}_Z [f_1 \vee \mathbf{EX} Z]$

- $\mathbf{AG} f_1 = \mathbf{gfp}_Z [f_1 \wedge \mathbf{AX} Z]$

- $\mathbf{EF} f_1 = \mathbf{lfp}_Z [f_1 \wedge \mathbf{EX} Z]$

- $\mathbf{AF} f_1 = \mathbf{lfp}_Z [f_1 \wedge \mathbf{AX} Z]$

- $\mathbf{E}[f_1 \cup f_2] = \mathbf{lfp}_Z [f_2 \wedge (f_1 \vee \mathbf{EX} Z)]$

- $\mathbf{A}[f_1 \cup f_2] = \mathbf{lfp}_Z [f_2 \wedge (f_1 \vee \mathbf{AX} Z)]$

Each CTL operator can be characterized as a least or greatest fixpoint of a predicate transformer:

Fixpoint Characterizations for CTL

- Additional steps are required to show that $E[f_1 \cup f_2]$ is the least such fixpoint.
1. Prove that $\tau(Z) = f_2 \vee (f_1 \wedge EX Z)$ is monotonic.
 2. Observe that τ is \cup -continuous and that $\text{Lfp } Z[\tau(Z)] = \cup_{i \in I} (False)$.
 3. Show that $E[f_1 \cup f_2] = \cup_{i \in I} (False)$. See next page.
 4. Conclude from steps 2 and 3 that $E[f_1 \cup f_2]$ is the least fixpoint of $\tau(Z) = f_2 \vee (f_1 \wedge EX Z)$.

It is straightforward to prove that $E[f_1 \cup f_2]$ is a fixpoint of $\tau(Z)$.

Proof:

$E[f_1 \cup f_2]$ is the least fixpoint of the functional $\tau(Z) = f_2 \vee (f_1 \wedge EX Z)$.

Lemma

Fixpoint Characterization of EU

Next, we show that $\mathbf{E}[f_1 \cup f_2] = \cup_i^i \tau_i(\text{False})$. We break this step into two parts:

- First, show that $\cup_i^i \tau_i(\text{False}) \subseteq \mathbf{E}[f_1 \cup f_2]$.
- Hint: Prove by induction that for all i , $\tau_i(\text{False}) \subseteq \mathbf{E}[f_1 \cup f_2]$. Use the fact that $\mathbf{E}[f_1 \cup f_2]$ is a fixpoint of $\tau(Z)$.

- Next, show that $\mathbf{E}[f_1 \cup f_2] \subseteq \cup_i^i \tau_i(\text{False})$.
- Hint: If $s_1 \models f_1 \cup f_2$, then there is a path $\pi = s_1, \dots, s_j, \dots$ such that $s_j \models f_2$ and for all $l < j$, $s_l \not\models f_1$. Show that $s_l \in \tau_l(\text{False})$.

Characterization of EU (Cont.)

$$\mathbf{E}[d \sqcup b] = \tau_\varepsilon(\text{False}) \text{ since } \tau_\varepsilon(\text{False}) = \tau_A(\text{False}).$$

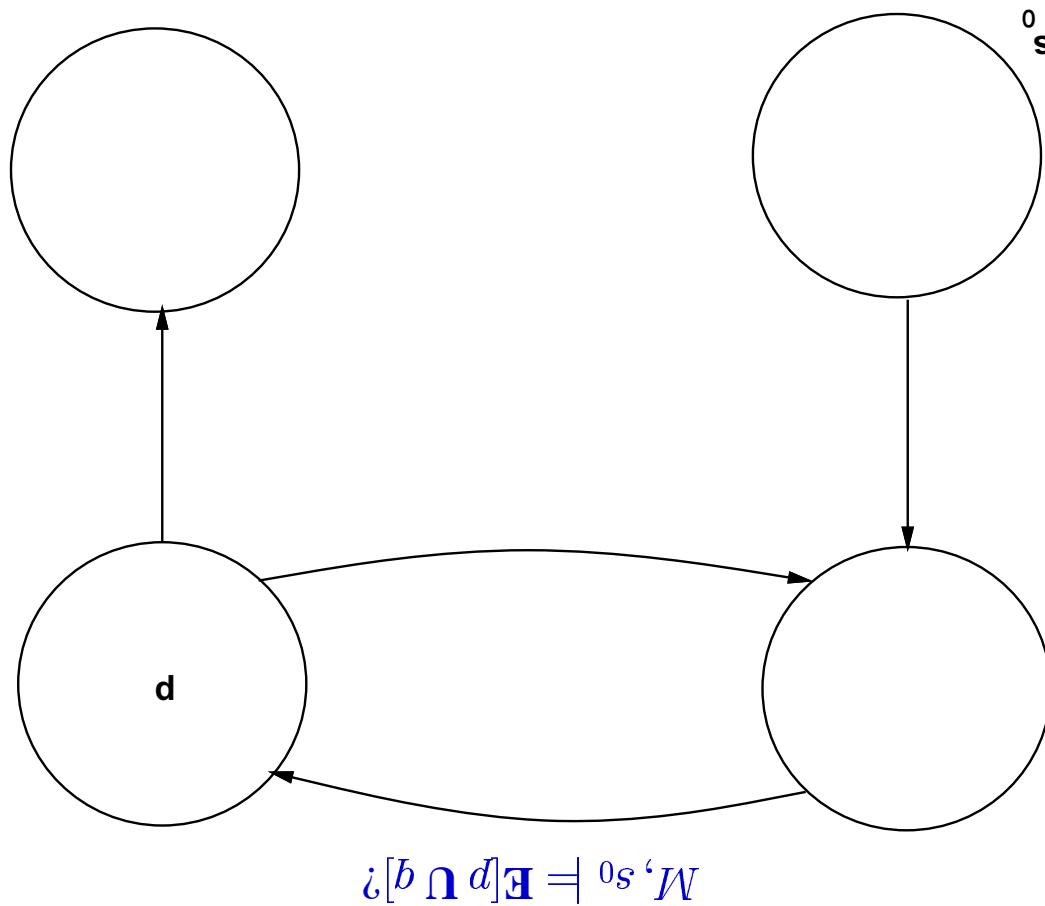

The figures demonstrate that the sequence of approximations $\tau_i(\text{False})$ converges to $\mathbf{E}[d \sqcup b]$.

$$\cdot (Z \mathbf{XX} \vee d) \wedge b = (Z \tau$$

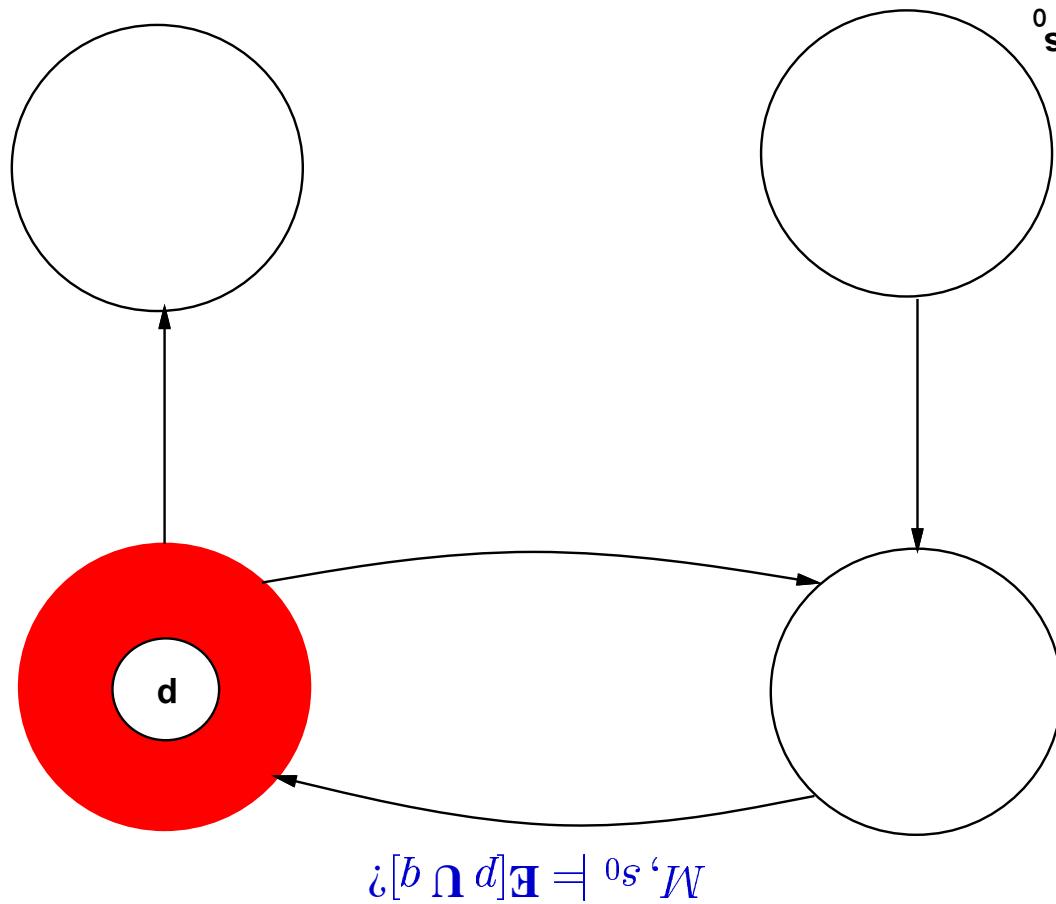

In this case the functional τ is given by

The next four figures show how $\mathbf{E}[d \sqcup b]$ may be computed for a simple Kripke structure.
