Abstract. This paper describes a new symbolic model checker, called NuSMV, developed as part of a joint project between CMU and Istituto per la Ricerca Scientifica e Tecnologica (IRST) whose goal is the reengineering, reimplementation and, to a limited extent, extension of the CMU SMV model checker. The core of this paper consists of a detailed description of the NuSMV functionalities, architecture, and implementation.

Key words: Symbolic model checking – Temporal logics – Automatic verification – Tools for technology transfer

1 Introduction

This paper describes the results of a joint project between Carnegie Mellon University (CMU) and Istituto per la Ricerca Scientifica e Tecnologica (IRST) whose goal is the development of a new symbolic model checker.1 The new model checker, called NuSMV, is designed to be a well-structured, open, flexible, and documented platform for model checking. To be usable in technology transfer projects, NuSMV was designed to be very robust, easy to modify, and close to the standards required by industry.

NuSMV is the result of the reengineering and reimplementation of the CMU SMV [26, 47] symbolic model checker. With respect to CMU SMV, NuSMV has been upgraded along three dimensions:

- From the point of view of the system functionalities, NuSMV has some features (e.g., multiple interfaces, LTL specifications) that enhance the user’s ability to interact with the system, and provide more heuristics, e.g., for achieving efficiency or partially controlling the state explosion.
- The system architecture of NuSMV is highly modular (thus allowing for the substitution or elimination of certain modules) and open (thus allowing for the addition of new modules). A further feature is that in NuSMV the user can control, and possibly change, the order of execution of some system modules.
- The quality of the implementation is much enhanced. NuSMV is a very robust and well documented system, whose code is (relatively) easy to modify.

The paper is organized as follows: in Sect. 2 we briefly introduce the logical framework underlying symbolic model checking; Sect. 3 describes the interaction with the system; Sect. 4 explains the functionalities provided by the system; Sect. 5 describes the NuSMV system architecture; Sect. 6 describes the NuSMV implementation features. Finally, Sect. 7 describes the results of some tests and future development directions.

NuSMV is available at the url http://afrodite. itc.it:1024/~nuSMV/.

2 Symbolic model checking

The most widely used verification techniques are testing and simulation. In the case of complex, asynchronous systems however, these techniques can cover only a limited portion of possible behaviors. A complementary verification technique is Temporal Logic Model Checking [23, 28, 51]. In this approach, the verified system is modeled as a finite state transition system, and the specifications are expressed in a propositional temporal logic. Then, by exhaustively exploring the state space of the state transition system, it is possible to check automatically if the specifications are satisfied. The termination of model checking is guaranteed by the finiteness of the model. One of the

1 The material presented in this paper is self-contained. This paper is readable with ordinary efforts for someone with some background in formal methods.
most important features of model checking is that when a specification is found not to hold, a counterexample (i.e., a witness of the offending behavior of the system) is produced.

2.1 Temporal logic

A finite state system can be described as a tuple:

\[ M = \langle S, I, R, L \rangle \]

where \( S \) is a finite set of states, \( I \subseteq S \) is the set of initial states, and \( R \subseteq S \times S \) is the transition relation, specifying the possible transitions from state to state. \( L \) is a function that labels states with the atomic propositions from a given language. Such a tuple is called a state transition graph or Kripke structure [44].

Temporal logics are used to predicate over the behavior defined by Kripke structures. A behavior in a Kripke structure is obtained starting from a state \( s \in I \), and then repeatedly appending states reachable through \( R \). We require that the transition relation \( R \) be total.\(^2\) As a consequence all the behaviors of the system are infinite. Since a state can have more than one successor, the structure can be thought of as unwinding into an infinite tree, representing all the possible executions of the system starting from the initial states. Figure 1 shows a state transition graph and its unwinding from the state labeled with "A".

![Fig. 1. A State Transition Graph and its unwinding](image)

Two useful temporal logics are Computation Tree Logic (called CTL) and Linear Temporal Logic (called LTL). They differ in how they handle branching in the underlying computation tree. In CTL it is possible to quantify over the paths departing from a given state. In LTL operators are intended to describe the properties of all possible computation paths.

The syntax of CTL formulas is given by the following rules:

1. Any atomic proposition is a CTL formula.
2. If \( \alpha \) and \( \beta \) are CTL formulas, then \( \alpha \land \beta \) and \( \neg \alpha \) are CTL formulas, where \( \land \) is any Boolean connective \((\land, \lor, \ldots)\).
3. If \( \alpha \) and \( \beta \) are CTL formulas, then \( \text{EX} \alpha, \text{EG} \alpha, \text{E}[\alpha \lor \beta] \) are CTL formulas.

Figure 2 describes the intuitive meaning of CTL formulas. \( \text{EX} \alpha \) means that there exists (E) a path starting from a state \( s_0 \in S \) in which in the next (X) state \( \alpha \) holds. \( \text{EG} \alpha \) means that there exists a path starting from a state \( s_0 \) in which globally (G) \( \alpha \) holds. \( \text{E}[\alpha \lor \beta] \) there exists a path starting from a state \( s_0 \) in which \( \alpha \) holds until (U) \( \beta \) holds. The other CTL operators (e.g., \( \text{AF} \alpha \), meaning for all paths eventually \( \alpha \)) can be derived from these three according to the rules listed in Table 1.

The syntax of LTL formulas is the following.

1. Any atomic proposition is an LTL formula;
2. If \( \alpha \) and \( \beta \) are LTL formulas, then \( \alpha \land \beta \) and \( \neg \alpha \) are LTL formulas, where \( \land \) is any Boolean connective \((\land, \lor, \ldots)\).
3. If \( \alpha \) and \( \beta \) are LTL formulas, then \( \text{X} \alpha, \text{G} \alpha, [\alpha \lor \beta] \) are LTL formulas.

The model checking problem can be formally formulated as follows. Given a Kripke structure \( M \) and a temporal logic formula \( \varphi \), find the set of all states that satisfy \( \varphi \), namely the set of states

\[ \{ s \in S \mid M, s \models \varphi \} \]

We say that the system satisfies the specification provided that all the initial states are in the set \( \{ s \in S \mid M, s \models \varphi \} \):

\[ I \subseteq \{ s \in S \mid M, s \models \varphi \} \]

Each CTL formula \( \varphi \) is identified by the set of states where it holds, \( \{ s \in S \mid M, s \models \varphi \} \). CTL operators may be characterized as a least or a greatest fixpoint of an appropriate predicate transformer [12]:

\[ \text{EG} \alpha = \text{gfp}_p[\alpha \land \text{EX} \beta] \]

\[ \text{E}[\alpha \lor \beta] = \text{lfp}_p[\beta \lor (\alpha \land \text{EX} \beta)] \]

This suggests an algorithm for symbolic model checking which is driven by the structure of the formula. For example, the computation of \( \text{E}[\alpha \lor \beta] = \text{lfp}_p[\beta \lor (\alpha \land \text{EX} \beta)] \)

![Fig. 2. The meaning of temporal modalities](image)
EXZ) corresponds to the following iterations:

\[ s_0 = \bot \]
\[ s_1 = \beta \lor (\alpha \land EX(\bot)) = \beta \]
\[ s_2 = \beta \lor (\alpha \land EX(\beta)) \]
\[ s_3 = \beta \lor (\alpha \land EX(\beta \lor (\alpha \land EX(\beta)))) \]

... Iterators continue until \( s_{i+1} = s_i \). The existence of least and greatest fixedpoints is guaranteed by the monotonicity of the predicate transformers and by the finiteness of the domain [12].

### 2.2 Symbolic representation of Kripke structures

The first model checking algorithms used an explicit representation of the Kripke structure as a labeled, directed graph [23, 28, 51]. A major improvement was achieved with the use of symbolic representations [12, 29, 47, 49, 59], based on the use of Ordered Binary Decision Diagrams [7, 8] (BDDs for short). BDDs are a representation for Boolean formulas, which is canonical once an order on the variables has been established. Figure 3 depicts the BDD for the Boolean formula \( (a_1 \leftrightarrow a_2) \land (b_1 \leftrightarrow b_2) \), using the variable ordering \( a_1, a_2, b_1, b_2 \). Solid lines represent “then” arcs (the corresponding variable has to be considered positive), dashed lines represent “else” arcs (the corresponding variable has to be considered negative). Paths from the root to the node labeled with “1” represent the satisfying assignments of the represented Boolean formula (e.g., \( a_1 \leftarrow 1, a_2 \leftarrow 1, b_1 \leftarrow 0, b_2 \leftarrow 0 \)).

Intuitively, a state of the system is symbolically represented by an assignment of Boolean values to the set of state variables. A Boolean formula (and thus its BDD) is a compact representation of the set of states represented by the assignments which make the formula true. Similarly, the transition relation can be expressed as a Boolean formula in two sets of variables, one relative to the current state and the other relative to the next state.

This makes it possible to represent predicate transformers and fixedpoints as BDDs. The basic Boolean operations are handled by means of standard algorithms for computing Boolean connectives with BDDs [7, 8], and fixpoint algorithms can be easily implemented in terms of basic BDD operations [12, 47].

The basic computation step in the previously described predicate transformers is the computation of the states satisfying EXa. Let \( \alpha(x) \) be a Boolean formula on the Boolean variables x, where x is a vector of Boolean state variables, representing the set of states satisfying \( \alpha \). The set of states satisfying EXa can be computed as:

\[
(\text{EX}\alpha)(\bar{x}) = \exists \bar{x}'. (\alpha(\bar{x})|\bar{x}'/\bar{x}) \land \mathcal{R}(\bar{x}, \bar{x}')
\]

Where with \( \alpha(\bar{x})|\bar{x}'/\bar{x} \) we mean the simultaneous substitution in \( \alpha(x) \) of variables \( \bar{x} \) with the corresponding variables \( \bar{x}' \). This operation, called Relational Product [47], is performed as an atomic operation on BDDs.

The set \( \{s \in S | M, s \models \varphi \} \) can be computed using basic BDDs operations plus fixpoint characterization of the CTL operators. Formally, the check which determines whether the model verifies a property \( \varphi \) (see (2)) reduces to the following check between BDDs:

\[ \neg \varphi \land I = \bot \]

### 2.3 Fields of application

The use of BDDs (i.e., the implicit representation of the transition system) makes it possible to verify very large...
systems (larger than $10^{20}$ states [11, 12, 47]). Symbolic model checking has been successful in various fields, allowing the discovery of design bugs that were very difficult to highlight with traditional techniques. Some of the most significant results are given below (an extensive discussion of the applications of symbolic model checking can be found in [27]):

- in [22] the authors applied this technique to verify the cache coherence protocol described in the IEEE Futurebus+ Standard 896.1.1991. They found a number of previously undetected and potential errors in the design of the protocol.
- in [46, 47] the authors verified the cache consistency protocol developed at Encore Compute Corporation for their Gigamax distributed multiprocessor.
- in [31] the cache coherence protocol of the Scalable Coherent Interface, IEEE Standard 1596-1992 was verified, and several errors were found.
- in [1] the authors verified part of a preliminary version of the system requirement specifications of TCAS II (Traffic Alert and Collision Avoidance System II). TCAS II is an aircraft collision avoidance system required on most commercial aircraft in United States.
- in [18, 39] model checking techniques are used in the verification of a railway interlocking system.

3 NuSMV: Look and feel

3.1 The SMV specification language

The current NuSMV input language [19] is essentially the same as the CMU SMV input language [26, 47]. The NuSMV input language is designed to allow for the description of finite state systems. The only data types provided by the language are Booleans, bounded integer subranges, and symbolic enumerated types. Moreover, NuSMV allows for the definitions of bounded arrays of basic data types.

The description of a complex system can be decomposed into modules, and each of them can be instantiated many times. This provides the user with a modular and hierarchical description, and supports the definition of reusable components. Each module defines a finite state machine. Modules can be composed either synchronously or asynchronously using interleaving. In synchronous composition a single step in the composition corresponds to a single step in each of the components. In asynchronous composition with interleaving a single step of the composition corresponds to a single step performed by exactly one component. The NuSMV input language allows us to describe deterministic and non deterministic systems.

An NuSMV program can describe both the model and the specification. Figure 4 gives a small example of a NuSMV program. The example in Fig. 4 is a model of a 3 bit binary counter circuit. It illustrates the definition of reusable modules and expressions. The module counter_cell is instantiated three times, with names bit0, bit1 and bit2. The module counter_cell has a formal parameter carry_in. In the instantiation of the module, actual signals (1 for the instance bit0, bit0.carry_out for the instance bit1, and bit1.carry_out for the instance bit2) are plugged in for the formal parameters, thus linking the module instance to the program (a module can be seen as a subroutine). The property that we want to check is “invariantly eventually the counter counts till 8” which is expressed in CTL using the design state variables as “AG AF bit2.carry_out”.

It is also possible to specify the transition relation and the set of initial states of a module by means of propositional formulas, using the keywords TRANS, and INIT respectively. This provides the user with a lot of freedom in designing systems. In Fig. 5 there is an equivalent definition of module counter_cell using propositional formulas.

With respect to CMU SMV, the input language of NuSMV has been extended to allow for the specification of properties expressed in LTL and the specifications of invariants [19].

```plaintext
MODULE main
VAR
  bit0 : counter_cell(1);
  bit1 : counter_cell(bit0.carry_out);
  bit2 : counter_cell(bit1.carry_out);
SPEC
  AG AF bit2.carry_out

MODULE counter_cell(carry_in)
VAR
  value : boolean;
ASSIGN
  init(value) := 0;
  next(value) := value + carry_in mod 2;
DEFINE
  carry_out := value & carry_in;

Fig. 4. A simple NuSMV program
```

```plaintext
MODULE counter_cell(carry_in)
VAR
  value : boolean;
INIT
  value = 0
TRANS
  next(value) <= ((value & carry_in) | (value & !carry_in))
DEFINE
  carry_out := value & carry_in;

Fig. 5. An equivalent definition of module counter_cell of the example described in Fig. 4
```
3.2 Interaction with NuSMV

NuSMV has both a batch and an interactive mode. The batch mode offers a built-in method for dealing with the system in which computations are activated according to a fixed predefined algorithm. The batch mode provides an interaction with the system that is essentially the same provided by CMU SMV.

In the interactive mode computation steps are activated by commands executed by a command line interpreter, thus allowing for the modification of the predefined model checking algorithm. The definition of the interactive shell required the decomposition of the model checking algorithm into small basic computation steps (e.g., parsing, model construction, reachability analysis, and model checking). In the current version of the system, each of them corresponds to a command that implements a different functionality.

The three modes of interaction with the NuSMV system, namely, the interactive shell, the batch mode and the graphical user interface are described below.

3.2.1 The NuSMV interactive shell

In this mode the system enters a read-eval-print loop. The user can activate the various NuSMV computation steps as system commands with different options. These steps can therefore be invoked separately, possibly undone, or repeated. These steps include the construction of the model in different ways and the model checking of specifications.

The NuSMV interactive shell allows for the full configuration of the BDD options. For instance, several automatic variable ordering methods and cache configuration mechanisms can be suitably tuned according to the application.

Moreover, the NuSMV interactive shell provides the user with a script language that makes it possible to define different model checking algorithms that can be invoked as model checking tactics. These algorithms are provided via parameterized scripts.

The interactive shell of NuSMV is activated from the system prompt as follows ("NuSMV >" is the default prompt that NuSMV prints out to indicate that it is ready to evaluate commands):

\[
\text{system_prompt} > \text{NuSMV -int}
\]

NuSMV release 1.0 (compiled 11-Nov-98 at 8:29 PM)

In Fig. 6 we can see a typical interaction with NuSMV through the interactive shell. The file "counter.smv"

---

5 The output was slightly modified to make it more readable.

Fig. 6. A typical interaction with NuSMV via the interactive shell
contains the example depicted in Fig. 4. The verification process in NuSMV can be decomposed into the following sequence of basic steps.

1. The first step towards verification is reading the model. This is performed by typing the NuSMV command read_model. This command takes as argument a file name containing the model specification. After the correct execution of this command an internal representation of the read file is built and stored.

2. The second step consists in transforming the hierarchical description into a flattened description. This is performed by typing the command flatten_hierarchy. After the correct execution of this command all the information needed to build the automaton is separated out (e.g., the variable names, their range, a symbolic representation of the initial states and of the transition relation of the flattened system).

3. The third step consists in the encoding of the scalar variables into Boolean variables. The NuSMV command build_variables is responsible for this task. It takes an optional argument specifying a file containing the ordering in which the variables have to be built. As a default, the order of variables used by NuSMV corresponds to the order in which the variables appear in a depth-first traversal of the hierarchy.

4. The fourth step consists in the compilation of the structures built by the flatten_hierarchy into BDDs using the encoding performed by build_variables. During this step some checks are performed that avoid circular dependencies in assignments and multiple definitions. The NuSMV command that implements this step is build_model. This command has an option specifying the partitioning method to be used, i.e., monolithic, conjunctive, or disjunctive (see Sect. 4). It is possible to build first the transition relation in different formats and then choose the most appropriate to the specific problem.

5. The fifth step deals with the fairness constraints. This command can be executed only when all the previous commands have been executed. This is due to the fact that fairness constraints are CTL formulas whose evaluation uses a previously computed transition relation.

After these five steps, the internal representation of the automaton is available to perform model checking.

6. It is possible to compute the set of reachable states, via the compute_reachable command. This allows the user to simplify the evaluation of all the specifications by restricting the search only to reachable states.

7. It is possible to start the verification of CTL specifications (via the check_spec command), of LTL specifications (via the check_ltlspec command), and of invariants (via the check_invar command). All these commands, if called with no arguments, apply to the specifications of the respective type, if any, listed in the source file. Optionally a CTL, LTL or propositional formula can be given as an argument. In the transcript of Fig. 6 first we check the property AG AF bit2.carry_out (the execution of check_spec without arguments, thus verifying the properties listed in the input file). Then we check the property AG AX bit2.carry_out (invariantly in the next state bit2.carry_out is 1). This property appear to be false, and a counterexample exploiting why the formula is not verified is computed and printed out.

3.2.2 The NuSMV batch mode

In this modality the system behaves mostly like the original CMU SMV. It performs some of the steps described previously in a fixed sequence. The sequence can be modified via command line options that enable different computations at fixed positions.

In the batch mode the system executes the first five steps previously described. The computation of the reachable states can be enabled before the computation of fairness constraints via the -f command line option. After the first five steps, the system looks for specifications in the source file, following the verification of CTL formulas, quantitative characteristics, LTL formulas and finally the invariants, if any. If the reordering of variables has been enabled via the -reorder command line option at the end of the computation, the reordering of variables starts and the generated ordering is saved into a file.

3.2.3 The NuSMV graphical user interface

On top of the interactive shell a graphical user interface (GUI from now on) was developed. The GUI is a separate process and communicates with NuSMV via the interactive shell.

From the GUI it is possible to edit and to modify the file containing the model description. The editor window provides the user with basic editing functionalities, such as copy and paste of blocks of text. Figure 7 gives a snapshot of the editor window. The NuSMV GUI allows for the modification of the options in a menu-driven way. A snapshot of the window for setting system options is the small window in Fig. 9. Moreover, the GUI offers a formula editor that helps the user in writing new specifications (see Fig. 8). Depending on the kind of formula to verify, various buttons corresponding to temporal modalities and/or Boolean connectives are activated. For instance in Fig. 8 a CTL specification was chosen (the radio-button relative to CTL formulas is selected), and all the Boolean connectives and the CTL operator buttons are active.

---

6 This file can be generated by hand by the user or automatically by activating the automatic variable ordering to reduce the size of the BDDs and saving the results with the write_order command.
4 System functionalities

The functionalities provided by NuSMV are described below. They are grouped in standard, advanced and user functionalities.

4.1 Standard functionalities

NuSMV offers all the standard model checking functionalities. A brief summary is reported below.

Encoding. In general it is very useful to represent systems using enumerated types. As symbolic algorithms work on Boolean variables, there is the need to encode propositions about non-Boolean variables in the space of Boolean variables. There are different ways to perform this task. At the moment NuSMV provides the encoding used in CMU SMV, which represents a finite range variable with a sequence of Boolean variables. Consider a state variable $x$ that can assume the values $\{a, b, c, d, e\}$. The propositions on the possible values of $x$ can be encoded with three Boolean variables $x_0$, $x_1$ and $x_2$, as shown in Table 2. Notice that the value assigned to the Boolean variable $x_2$, in the case of $x \in \{b, c, d\}$, is indifferent, and it can be either 0 or 1.\footnote{This has the effect that for example the BDD representing the encoding of $x = c$ is only in terms of the Boolean variables $x_0$ and $x_1$.} The Boolean variables used to encode a scalar variable are grouped together, and are considered as a single block of variables in the BDD package. Other encoding policies can be more appropriate for variables of a different kind. For example, word-level encodings are useful for the analysis of data paths [25]. Moreover, the constraint of grouping the Boolean variables together can be relaxed. Some of these policies will be codified in further releases of NuSMV.

Reachability analysis. NuSMV, (similarly to CMU SMV), offers an enhanced algorithm for reachability analysis. The standard way to perform the computation of the reachable states $\text{Reachable}(I)$, starting from the initial states $I$, is:

$$\text{Reachable}(I) = R_k(x)$$

where $k$ is the minimum integer such that $R_k(x) = R_{k+1}(x)$, and $R_k(x)$ is recursively defined as:

$$R_0(x) = I$$
$$R_{k+1}(x) = \left( x \mapsto (R_k(x) \land T(x, x')) \right)[x/x'] \cup R_k(x)$$

where $x$ is the vector of state variables, $T(\cdot, \cdot)$ is the transition relation, and $R_k(x)$ is the set of states reached in $k$ or fewer steps.

The computation of the states reachable in $k+1$ steps can be performed by considering only the frontier set...
\[ F_k(x) = R_k(x) \land R_{k-1}(x) \]
\[ R_{k+1}(x) = (\exists x'. (F_k(x) \land T(x, x')))[x/x'] \cup R_k(x) \]

We are planning to introduce new optimizations to the computation of the set of reachable states, such as the use of don't care sets. The set of reachable states can be used to simplify the following model checking computations.

**Fair CTL model checking.** NuSMV, similarly to CMU SMV, uses the algorithms presented in [12] as the basis for fair CTL model checking. These algorithms are essentially based on a fixpoint characterization of temporal modalities and they work quite well in practice. If the set of reachable states has already been computed, the set of reachable states is used in the evaluation of CTL formulas. This allows us to restrict the search to reachable states only.

---

Fig. 9. The NuSMV GUI and the options setting window

---

Check for transition relation totality. In NuSMV it is possible to check the totality of the transition relation. The check is performed by means of basic model checking operations:

\[ T(\cdot, \cdot) \text{ is total if and only if } \text{EX}(\top) = 1 \]

This functionality is very useful if the keywords TRANS or INVAR\(^9\) are used to specify the transition relation. In these cases it is in fact possible to introduce deadlock states.

**Counterexamples generation.** One of the most important functionalities of symbolic model checking is the ability to generate a counterexample for unsatisfied properties. The algorithms used in NuSMV as a basis to perform the computation of counterexamples are the same as those implemented in CMU SMV and are those presented in [24].

---

\(^8\) If \(A\) is a set, then with \(\bar{A}\) we mean the complement set.

\(^9\) INVAR specifies time invariants using propositional formulas.
4.2 Advanced Functionalities

NuSMV provides advanced model checking functionalities, including specialized algorithms for the verification of invariants, and heuristics aiming at the reduction of the state explosion problem. In the following these functionalities are briefly explained.

**Bounded CTL.** NuSMV allows expressing specifications in real-time CTL (RTCTL) [33]. For example, it is possible to express that $\alpha$ always leads to $\beta$ in 0 to 4 time units with the RTCTL specification\(^{10}\):

$$\text{AG}(\alpha \rightarrow \text{AR}^{0,4} \beta)$$

It is assumed that a time unit corresponds to a step. This functionality is the same as in CMU SMV.

**Invariant checking.** An important class of CTL formulas is invariants, i.e., formulas of the form $\text{AG} \alpha$, where $\alpha$ is a propositional formula. The semantics of these kinds of formulas is that $\alpha$ is true in all reachable states. The computation of these kinds of formulas is based on a fixpoint characterization [12]:

$$\text{AG} \alpha = \text{gf} \text{p}_{\alpha} [\alpha \land \text{AX} Z]$$

This approach is not very direct, and can be quite inefficient. If the set of reachable states has been previously computed, then an invariant can be simply checked by performing a test of set inclusion between the states represented by $\alpha$ and the set of reachable states:

$$\text{Reachable}(Z) \subseteq \alpha$$

NuSMV offers the possibility of checking invariants using either this or the standard model checking technique. These functionalities are the same as in CMU SMV. Moreover, NuSMV, with respect to CMU SMV, has a specialized routine for checking invariants on the fly. This is performed by verifying the following condition at each step $k$ of the reachability analysis:

$$R_k(\bar{x}) \subseteq \alpha$$

where $R_k(\bar{x})$ is the set of states reachable in $k$ or fewer steps. If this test fails, then the invariant is not verified, and a counterexample leading to a state not satisfying the property is provided.

**Quantitative characteristics computation.** In NuSMV it is possible to compute quantitative information on the Kripke structure [14, 15]. In particular, it is possible to compute the exact bound on the delay between two specified events, expressed as CTL formulas:

$$\text{MIN}[\alpha, \beta] \quad \text{MAX}[\alpha, \beta]$$

The $\text{MIN}[\alpha, \beta]$ computes the set of states reachable from $\alpha$. When a state satisfying $\beta$ is encountered, we return the number of steps taken so far. If a fixpoint is reached an no state satisfying $\beta$ is found, then $\text{INFINITY}$ is returned.

$\text{MAX}[\alpha, \beta]$ has the dual interpretation, and returns the length of the longest path from a state in $\alpha$ to a state in $\beta$. If there exists an infinite path beginning in a state in $\alpha$ that never reaches a state in $\beta$, then $\text{INFINITY}$ is returned.

**This functionality is the same as in CMU SMV.**

**LTL model checking.** LTL is important because it allows us to express properties, such as fairness,\(^{11}\) which are not expressible in CTL. Furthermore, LTL can be useful to perform selective analysis, namely, to specify the paths of interest.

NuSMV supports LTL model checking implementing the algorithm presented in [32]. An LTL formula is automatically converted into a tableau [45], which is then used to extend the original model in synchronous product. The result is provided by checking the validity of an automatically generated CTL formula from the LTL specification in the extended model.

The loose integration presented in [32] allows for the use of CMU SMV as a black box by generating a new input file containing both the original description of the system and the code implementing the tableau. However, for each LTL formula to be verified, the verification process has to be restarted from scratch, starting from the parsing of the newly generated input file. In NuSMV, the tableau generation is tightly integrated. If more than one LTL property is specified, only the generation of the corresponding tableau is required, hence avoiding, each time the generation of the whole model. The generated tableau is parsed in, compiled into BDD and synchronously composed with the original model.\(^{12}\)

**Partitioning of the model.** One of the most important operations in model checking is the relational product:

$$\exists \bar{x}. (S(\bar{x}) \land T(\bar{x}, \bar{x}'))$$

which computes the set of states reachable from $S(\bar{x})$ through the transition relation $T(\cdot, \cdot)$. This operation can be performed as a single step by most BDD packages. Although it works quite well in practice, this operation has worst-case exponential complexity [47]. The transition relation is said to be *monolithic*, as it consists of a single BDD.

\(^{10}\) In the NuSMV input language this specification is written as $\text{SPEC A5(\alpha \rightarrow A0B 0..4 \beta)}$

\(^{11}\) A typical fairness property is “if a process is infinitely often executable then it is infinitely often executed”, that corresponds to the LTL formula: “$\text{GF}(\text{P.executable}) \rightarrow \text{GF}(\text{P.executed})$”.

\(^{12}\) Other model checkers [6, 41] are able to perform LTL mode checking. In VIS [6], for example, it is possible to perform LTL model checking by using the language emptiness feature [60], but the user has to write by hand the automaton representing the acceptance condition of the LTL formula, and for each formula a different input file has to be generated and the computation must restart from scratch.
In many practical cases, building the BDD for $T(\cdot, \cdot)$ may not be feasible. In many cases, however, it is possible to exploit the structure of the system and build the transition relation as a list of small BDDs, called clusters, which are implicitly disjoined (e.g., with an asynchronous model of concurrency) or conjoined (e.g., with synchronous systems) [9–11].

\[
T(\cdot, \cdot) = \bigvee_i T_i(\cdot, \cdot) \text{disjunctive}
\]

\[
T(\cdot, \cdot) = \bigwedge_i T_i(\cdot, \cdot) \text{conjunctive}
\]

In both cases the monolithic relational product is reduced to a sequence of disjunctively/conjunctively composed relational products on the clusters.

With a disjunctively partitioned transition relation, the relational product can be computed as follows:

\[
\exists \bar{x}. (S(\bar{x}) \land T(\bar{x}, \bar{x}')) = \exists \bar{x}. \left( S(\bar{x}) \land \bigvee_i T_i(\bar{x}, \bar{x}') \right) = \bigvee_i \exists \bar{x}. (S(\bar{x}) \land T_i(\bar{x}, \bar{x}'))
\]

In this way the relational product can be computed without ever building the BDD for the monolithic transition relation by distributing the existential quantification over disjunctions. The relational product is decomposed into a series of relational products involving relatively small BDDs.

For synchronous systems, NuSMV implements techniques based on early variable quantifications [9, 10, 59]. The basic idea is to find an ordering of the partitions $T_i(\cdot, \cdot)$ such that the quantification can be pushed inside the formula as much as possible, thus allowing relational products between small BDDs and existential quantification on a small number of variables, and thus reducing the complexity of the whole operation:

\[
\exists \bar{x}. (S(\bar{x}) \land T(\bar{x}, \bar{x}')) = \exists \bar{x}. \left( S(\bar{x}) \land \bigwedge_i T_i(\bar{x}, \bar{x}') \right) = \exists \bar{x}_1. \left( \exists \bar{x}_2. \left( \ldots \left( \exists \bar{x}_n. (S(\bar{x}) \land T_n(\bar{x}, \bar{x}')) \right) \right) \right) \land \ldots \land \bigwedge_i T_i(\bar{x}, \bar{x}')
\]

where $\bar{x}_1$ are disjoint sets of variables, $\bar{x}_i$ being the set of variables that the $T_j(\cdot, \cdot)$ with $j > i$ depends on, but $T_i(\cdot, \cdot)$ does not depend on.

NuSMV allows the user to perform model checking using the monolithic transition relation or the disjunctively or conjunctively partitioned transition relation. For conjunctive partitioning, the heuristics described in [35] and in [53] are available. They allow the user to compute the clusters for the conjunctively partitioned transition relation.

### 4.3 User functionalities

The quality of interaction with the system is very important in several phases of the verification task. NuSMV provides various user functionalities. In the following these functionalities will be briefly explained.

#### Counterexample navigation

The ability to generate counterexamples for properties that are not verified is very useful in the design phase and is common to the majority of model checkers. In NuSMV it is also possible to navigate and inspect counterexamples, similarly to what a programmer can do in a debugger for a programming language. The user can jump from state to state, possibly between different counterexamples, and evaluate CTL expressions in a given state of a counterexample, thus generating a possible new debug trace. These functionalities are available via commands of the interactive shell.

**On the fly modification of the model.** The user might want to try to modify the model (e.g., to try to fix a bug) or add new fairness constraints without restarting the computation from scratch. In NuSMV this can be done using shell commands that allow the user to modify the model interactively. The user can impose a new constraint on the set of initial states, the set of invariants or on the transition relation. Let $I$ be the set of initial states, $Inv$ the set of invariants, $T(\cdot, \cdot)$ the transition relation, and $H$ the set of fairness constraints. Then the modifications act as follows:

\[
I := I \cap I_a \\
Inv := Inv \cap Inv_a \\
T(\cdot, \cdot) := T(\cdot, \cdot) \cap T_a(\cdot, \cdot) \\
H := H \cup \{h_a\}
\]

where $I_a$, $Inv_a$ are the added set of initial states and invariant states respectively. $T_a(\cdot, \cdot)$ is the added transition relation and $h_a$ is the new fairness constraint. Moreover, NuSMV allows the user to undo the modifications and restore the original status of the system. This is useful in case the user wants to try further modifications.

#### Online help

NuSMV features an online help functionality. Each command provided by the interactive shell has a short help note briefly describing its options. Moreover, a complete description of each command is available via the NuSMV interactive shell in text format and, via a web browser, in HTML format.

### 5 System architecture

One of the most important features of NuSMV is that it is an open system, and can be easily modified, customized or extended. This is possible because the architecture of NuSMV is structured and organized in modules. Each module implements a set of functionalities and communicates with the others via a precisely defined interface. A schema of the system architecture can be found.

---

13 A similar philosophy of developing an open platform is advocated by the authors of the CADP tool-box [34].
different kinds of variables. Currently, only the standard CMU SMV encoding is possible, but there are plans to integrate into this architecture other forms of encoding, e.g., those used in Word-Level SMV [25].

The semantic check module. This module is responsible for all the necessary semantic checks on the model, e.g., the absence of circular definitions [47].

FSM Compiler. This module provides the routines for constructing and manipulating FSMs at the BDD level. The FSMs can be represented in monolithic or partitioned form [9–11]. The heuristics used to perform the conjunctive partitioning of the transition relation and reordering of the clusters [35, 53] were developed to work at the BDD level, independently of the input language. This is a precise design choice: since NuSMV is intended to be applicable to a wide range of domains, for which the current input language might not be appropriate, it is important that the heuristics do not depend on the input language. Note that for a specialized model checker this might not be a suitable choice. For instance, since VIS [6] is highly specialized for hardware, its heuristics were developed to work directly on the BLIF format [56], which is a netlist. The interface to other modules is given by the primitives for the computation of image and pre-image of set of states. These primitives are independent from the method used to represent the transition relation (monolithic, conjunctive or disjunctive).

Fairness. This module deals with the fairness constraints. It provides the model checking module with the information contained in the fairness constraints, if any.

Model Checking. This module provides all the (RT)CTL model checking functionalities, such as reachability and model checking routines, routines that perform computation of quantitative characteristics, and check invariants on the fly. All these routines are based on the image and pre-image computation primitives, and are independent of the particular method used to represent the FSM.

Explanation module. The routines for counterexamples and witnesses generation and inspection. Counterexamples and witnesses can be produced with different levels of verbosity, in the form of reusable data structures, and can subsequently be inspected and navigated. These routines are independent of the particular method used to represent the FSM.

LTL module. The LTL module is a separate module that calls an external program that translates the LTL formula into a tableau suitable to be loaded into NuSMV.

---

14 A netlist is a representation of a design at the structural level. An FSM can be viewed as a behavioral description of the design. A netlist is much closer to the implementation of the design than a simple FSM. A netlist is essentially the data structure used by many logic synthesis tools, like VIS [6], to internally represent designs derived from HDL descriptions.
This program also generates a new CTL formula to be verified on the synchronous product of the original system and the generated tableau. This module was plugged in on top of the other modules (e.g., the parser, the encoder, the FSM compiler, the model checking and the explanation modules), thus reusing a lot of the functionalities already present in the architecture.

**Kernel.** The kernel provides the low-level functionalities such as dynamic memory allocation, and manipulation of basic data structures (e.g., cons cells, hash tables). The kernel also provides all the basic BDD primitives, which are actually taken from the CUDD [57] BDD package. The CUDD package is a very complete BDD package, freely available on the Web. It provides all the basic BDD operations, plus a series of advanced BDD functionalities (such as various state of the art BDD variable reordering algorithms, the possibility of grouping together variables in such a way that the reordering algorithms treats them as a single element, algorithms to perform BDD minimization, approximation and decompositions, etc.). The CUDD package is integrated in NuSMV with a precisely defined interface. This makes it possible to replace the CUDD package with other state of the art BDD packages developed in the future, or with commercial BDD packages (such as the TiGeR [30] BDD package). The NuSMV kernel can be used as a black box, following coding standards that have been precisely defined.

**Interactive shell.** The interactive shell was designed on top of all the other modules. From the interactive shell the user has full access to all the functionalities provided by the system. The interactive shell is fully extensible, thus allowing for the development of new commands. (For more details see Sect. 3.2.1.)

**Graphical user interface.** The graphical user interface is a separate process, which communicates with NuSMV by sending textual commands to the interactive shell. It allows the user to inspect and set the value of the environment variables of the system, and provides full access to all the functionalities. Figures 7–9 show some snapshots of the graphical interface of NuSMV. (For more details see Sect. 3.2.3.)

### 6 Implementation

NuSMV was designed to be robust and easy to maintain and to modify. The features of the NuSMV implementation are listed below. They are grouped depending on the design task that they are intended to accomplish.

**Robustness.**
- NuSMV is written in ANSI C [55] and is POSIX [42] compliant. This makes the system portable to any compliant platform. At the moment the system has been successfully compiled on various operating systems and platforms (e.g., under Sun Solaris for SPARC and Intel X86, under SunOS 4.1.X, under various versions of the Linux operating system).
- NuSMV has been thoroughly debugged with Purify to detect memory leaks and runtime memory corruption errors. The use of this tool guarantees the elimination of runtime problems in all parts of the application, and thus the delivery of a more reliable and robust application.
- The kernel of NuSMV provides low-level functionalities, such as dynamic memory allocation, independently from the underlying operating system and hardware platform. Moreover, it provides routines for the manipulation of basic data structures such as cons cells, hash tables, arrays of generic types, and encapsulates the CUDD BDD package [57].

**Maintainability.**
- In order to implement the architecture depicted in Sect. 5, the source code of NuSMV has been separated into different packages. At the moment NuSMV is composed of 11 packages. Each package exports a set of routines that manipulate the data structures defined in the package and modify the options associated to the functionalities provided by the package itself. Moreover, each package is associated with a set of commands that can be interpreted by the NuSMV interactive shell. We have packages for model checking, FSM compilation, BDD interfacing, LTL model checking and kernel functionalities. New packages can be added relatively easily, following precisely defined rules.
- The source code of NuSMV is maintained using a tool for revision controls. We use the RCS [58] tool provided by GNU. It automates the storing, retrieval, logging and merging of revisions and provides a simple and user-friendly interface.
- In the coding, we have used an object-oriented programming style, following the ideas exploited by the VIS [6] system.
- The code of NuSMV is documented following the standards of the ext tool. This tool allows for the automatic extraction of the programmer manual from the source comments in the system code. The programmer manual is available in TExT or HTML format, in a way that is browsable by an HTML viewer. This tool is also used to generate the online help available through the interactive shell and via the graphical user interface.
- The user manual is written following the standard TExINFO [16]. This allows us to have the user manual

---

15 More information on this tool can be found at the url “http://www.puraetria.com”.
16 More information about the ext documentation tool can be found at the url “http://alumnum.caltech.edu/~sedwards/xtex.”
available in different formats (for instance \texttt{POSTSCRIPT}, \texttt{PDF}, \texttt{DVI}, \texttt{INFO}, \texttt{HTML}), directly from the NuSMV interactive shell, via an \texttt{HTML} viewer or in hardcopy.

7 Conclusions

We have presented the NuSMV symbolic model checker. The NuSMV architecture provides a precise distinction from the back-end (model checking algorithms, heuristics for optimal conjunctive partitioning, etc.) and the front-end (the input language). The NuSMV back-end is general purpose, and can be used not only for verifying hardware but also for verification in other fields in which systems can be modeled as an FSM (e.g., software, etc.).

The rest of this section compares the performance of NuSMV and CMU SMV, describes the development of a planner built on top of NuSMV, and some directions for future developments.

7.1 NuSMV vs. CMU SMV

The capabilities of NuSMV were tested on a series of examples taken from the literature, which were then used for a comparison with the original CMU SMV. Below is a brief description of the tests used and their sources:

- the \{4,8,10,11\}-bit alternating bit protocol by Armin Biere [4].
- a bounded retransmission (communication) protocol, by K. Havelund [40].
- the examples of the CMU SMV distribution.
- a model of the Shuttle Digital Autopilot, by Sergey Berezin.
- some models of the PCI Bus protocol, by Sergio Campos.
- a model of a production cell, by Kirsten Winter [61].
- a model of a batch reactor, by S.T. Probst [50].
- some models of part of a preliminary version of the system requirements specification of TCAS II (Traffic Alert and Collision Avoidance System II), by William Chan [1].

These examples can be found in the distribution of NuSMV. Table 3 lists the results of such a comparative test. For each test, we report the number of (current and next) Boolean variables necessary to represent the corresponding model (“\# of BDD vars”), and the memory\textsuperscript{17} and time required by the systems to analyze the model. We mark as time out the failure to solve the problems in 15000 seconds. For the examples marked with “(*)” a previously computed ordering file was provided to the system. The verification of the examples marked with a “(+)” required the modification of some of the parameters of the BDD package. The other symbols between parentheses are command line options passed to the model checkers: -f enables the computation of the set of reachable states (which is then used to restrict the search in model checking), while -cp \# enables conjunctive partitioning with the threshold of each partition set to \#. All these tests were performed on an Intel Pentium II 300 Mhz processor with 512 Mb of RAM under Linux Red Hat 5.0. The results listed in Table 3 show that NuSMV performs in most examples better (in 22 examples of the 39 listed with respect to speed and in 8 examples regarding memory occupation) than CMU SMV, especially for larger examples. This enhancement in performance is mainly due to the use of the state of the art CUDD BDD package. In the tests none of the enhanced capabilities not present in CMU SMV (e.g., enhanced partitioning methods), were used.

7.2 NuSMV is open: the MBP example

NuSMV has been and is still used as the kernel of MBP a planner based on model checking able to synthesize reactive controllers for achieving goals in non-deterministic domains [20, 21].\textsuperscript{18} MBP has been obtained by substituting or eliminating some of the NuSMV modules. In particular, the NuSMV parser module has been redone (the two input languages are different); the NuSMV instantiation module has been eliminated (at the moment, in MBP there is no concept of hierarchy); the NuSMV semantic check module has been redone; the NuSMV FSM compiler has been redone to reflect the way in which the MBP input language is compiled into BDDs [17]. All the other modules have been left unchanged, and are shared between the two systems. Finally, a new module, containing all the special purpose planning algorithms, has been added. This module provides routines based on the image and pre-image computation.

7.3 Future directions

To make the system more usable and improve its efficiency and expressiveness there are plans to introduce the following additional functionalities:

- A simulation functionality, which allows the user to acquire confidence with the correctness of the model before the verification of the properties.
- A sequential input language. The problem with the NuSMV language is that it is most amenable for hardware and hardware-like systems, while its ability to model software systems is left to the user. This leaves the user with the burden of a complex model generation activity. In general, this is hardly accept-

\textsuperscript{17} This is the maximum amount of memory allocated during state space generation and search, namely, the amount of memory allocated since the program starts to the end of the computation before freeing all the memory allocated.

\textsuperscript{18} See [37] for an introduction and a survey of planning as model checking.
able, as many specification languages (e.g., SDL) are intrinsically sequential. A possible new input language for NuSMV is VERUS [13].

- Forward CTL model checking. In symbolic model checking, CTL formulas are evaluated backward (the base operation is EX, see Sect. 2). New algorithms have been developed that allow performing evaluation of CTL formulas via a forward state traversal [43]. These algorithms allow for the verification of large systems that cannot be handled by the classical backward algorithms.

- Cone of influence reductions [3]. The idea is to simplify the model regarding the cone of influence of the formula to be verified, thus reducing the search space.

- Use of "reachability don't cares" (RDC) [63] to reduce the cost of CTL model checking.

- High density reachability analysis [54] and under and over-approximate reachability analysis [48]. These have shown in some cases, together with RDC, dramatic effects in the performance of CTL model checking.

- Optimizations for constraint-rich models [62], to enable the verification of systems with complex time-invariant constraints.

Some lines of research that are currently under study and whose results we plan to integrate inside NuSMV are specific reduction techniques for sequential systems, a set
