Remarks About Assignment 2

- Remember that object transformations are applied in the **reverse** order in which they appear in the code!
- Remember that transformation matrices are multiplied on the **right** and executed from right to left: $(R\ S\ T)v = R\ (S\ (T\ v))!$
- Look at the model solution (when it is out) and make sure you understand it before the midterm

Outline

- Light Sources
- Phong Illumination Model
- Normal Vectors

Lighting and Shading

- Approximate physical reality
- Ray tracing:
 - Follow light rays through a scene
 - Accurate, but expensive (off-line)
- Radiosity:
 - Calculate surface inter-reflection approximately
 - Accurate, especially interiors, but expensive (off-line)
- **Phong Illumination model** (this lecture):
 - Approximate only interaction light, surface, viewer
 - Relatively fast (on-line), supported in OpenGL

Radiosity Example

Restaurant Interior. Guillermo Leal, Evolucion Visual

Raytracing Example

Martin Moeck,
Siemens Lighting

Light Sources and Material Properties

- Appearance depends on
 - Light sources, their locations and properties
 - Material (surface) properties
 - Viewer position
- Ray tracing: from viewer into scene
- Radiosity: between surface patches
- Phong Model: at material, from light to viewer

Types of Light Sources

- **Ambient light**: no identifiable source or direction
- **Point source**: given only by point
- **Distant light**: given only by direction
- **Spotlight**: from source in direction
 - Cut-off angle defines a cone of light
 - Attenuation function (brighter in center)
- Light source described by a luminance
 - Each color is described separately
 - $I = [I_r \ I_g \ I_b]^T$ (I for intensity)
 - Sometimes calculate generically (applies to r, g, b)

Ambient Light

- Global ambient light
 - Independent of light source
 - Lights entire scene
- Local ambient light
 - Contributed by additional light sources
 - Can be different for each light and primary color
- Computationally inexpensive

$$\mathbf{I}_a = \begin{bmatrix} I_{ar} \\ I_{ag} \\ I_{ab} \end{bmatrix}$$

Point Source

- Given by a point p_0
- Light emitted equally in all directions

$$\mathbf{I}(p_0) = \begin{bmatrix} I_r(p_0) \\ I_g(p_0) \\ I_b(p_0) \end{bmatrix}$$

- Intensity decreases with square of distance

$$\mathbf{I}(p, p_0) = \frac{1}{|p - p_0|^2} \mathbf{I}(p_0)$$

Limitations of Point Sources

- Shading and shadows inaccurate
- Example: penumbra (partial “soft” shadow)
- Similar problems with highlights
- Compensate with attenuation

$$\frac{1}{(a + bd + cd^2)}$$

$d = \text{distance } |p - p_0|$
 $a, b, c \text{ constants}$

- Softens lighting
- Better with ray tracing
- Better with radiosity

Distant Light Source

- Given by a vector v
- Simplifies some calculations
- In OpenGL:
 - Point source $[x \ y \ z \ 1]^T$
 - Distant source $[x \ y \ z \ 0]^T$

Spotlight

- Most complex light source in OpenGL
- Light still emanates from point
- Cut-off by cone determined by angle θ

Spotlight Attenuation

- Spotlight is brightest along I_s
- Vector v with angle ϕ from p to point on surface
- Intensity determined by $\cos \phi$
- Corresponds to projection of v onto I_s
- **Spotlight exponent** e determines rate

$$I = \cos^e(\phi) = (v \cdot I_s)^e$$

Diagram correction [$u = \theta$, $f = \phi$]

for $e = 1$

for $e > 1$
curve narrows

Outline

- Light Sources
- Phong Illumination Model
- Normal Vectors

Phong Illumination Model

- Calculate color for arbitrary point on surface
- Compromise between realism and efficiency
- Local computation (no visibility calculations)
- Basic inputs are material properties and I , n , v :

I = vector to light source
 n = surface normal
 v = vector to viewer
 r = reflection of I at p
(determined by I and n)

Basic Calculation

- Calculate each primary color separately
- Start with global ambient light
- Add reflections from each light source
- Clamp to $[0, 1]$
- Reflection decomposed into
 - Ambient reflection
 - Diffuse reflection
 - Specular reflection
- Based on ambient, diffuse, and specular **lighting and material** properties

Ambient Reflection

- Intensity of ambient light uniform at every point
- Ambient reflection coefficient k_a , $0 \leq k_a \leq 1$
- May be different for every surface and r,g,b
- Determines reflected fraction of ambient light
- L_a = ambient component of light source
- Ambient intensity $I_a = k_a L_a$
- Note: L_a is **not** a physically meaningful quantity

Diffuse Reflection

- Diffuse reflector scatters light
- Assume equally all direction
- Called **Lambertian** surface
- Diffuse reflection coefficient k_d , $0 \leq k_d \leq 1$
- Angle of incoming light still critical

Lambert's Law

- Intensity depends on angle of incoming light

- Recall

\mathbf{l} = unit vector from light

\mathbf{n} = unit surface normal

θ = angle to normal

- $\cos \theta = \mathbf{l} \cdot \mathbf{n}$

- $I_d = k_n (\mathbf{l} \cdot \mathbf{n}) L_d$

$$I_d = \frac{k_d}{a + bq + cq^2} (\mathbf{l} \cdot \mathbf{n}) L_d$$

q = distance to light source,
 L_d = diffuse component of light

Specular Reflection

- Specular reflection coefficient k_s , $0 \leq k_s \leq 1$
- Shiny surfaces have high specular coefficient
- Used to model specular highlights
- Do **not** get mirror effect (need other techniques)

specular reflection

specular highlights

Shininess Coefficient

- L_s is specular component of light
- r is vector of perfect reflection of l about n
- v is vector to viewer
- ϕ is angle between v and r
- $I_s = k_s L_s \cos^\alpha \phi$
- α is shininess coefficient
- Compute $\cos \phi = r \cdot v$
- Requires $|r| = |v| = 1$
- Multiply distance term

Higher α is narrower

Summary of Phong Model

- Light components for each color:
 - Ambient (L_a), diffuse (L_d), specular (L_s)
- Material coefficients for each color:
 - Ambient (k_a), diffuse (k_d), specular (k_s)
- Distance q for surface point from light source

$$I = \frac{1}{a + bq + cq^2} (k_d L_d (\mathbf{l} \cdot \mathbf{n}) + k_s L_s (\mathbf{r} \cdot \mathbf{v})^\alpha) + k_a L_a$$

\mathbf{l} = vector from light

\mathbf{n} = surface normal

\mathbf{r} = \mathbf{l} reflected about \mathbf{n}

\mathbf{v} = vector to viewer

Outline

- Light Sources
- Phong Illumination Model
- Normal Vectors

Normal Vectors

- Summarize Phong

$$I = \frac{1}{a + bq + cq^2} (k_d L_d(\mathbf{l} \cdot \mathbf{n}) + k_s L_s(\mathbf{r} \cdot \mathbf{v})^\alpha) + k_a L_a$$

- Surface normal \mathbf{n} is critical
 - Calculate $\mathbf{l} \cdot \mathbf{n}$
 - Calculate \mathbf{r} and then $\mathbf{r} \cdot \mathbf{v}$
- Must calculate and specify the normal vector
 - Even in OpenGL!
- Two examples: plane and sphere

Normals of a Plane, Method I

- Method I: given by $ax + by + cz + d = 0$
- Let p_0 be a known point on the plane
- Let p be an arbitrary point on the plane
- Recall: $u \cdot v = 0$ iff u orthogonal v
- $n \cdot (p - p_0) = n \cdot p - n \cdot p_0 = 0$
- Consequently $n_0 = [a \ b \ c \ 0]^T$
- Normalize to $n = n_0/|n_0|$

Normals of a Plane, Method II

- Method II: plane given by p_0, p_1, p_2
- Points may not be collinear
- Recall: $u \times v$ orthogonal to u and v
- $n_0 = (p_1 - p_0) \times (p_2 - p_0)$
- Order of cross produce determines orientation
- Normalize to $n = n_0/|n_0|$

Normals of Sphere

- Implicit Equation $f(x, y, z) = x^2 + y^2 + z^2 - 1 = 0$
- Vector form: $f(p) = p \cdot p - 1 = 0$
- Normal given by **gradient vector**

$$\mathbf{n}_0 = \begin{bmatrix} \frac{\partial f}{\partial x} \\ \frac{\partial f}{\partial y} \\ \frac{\partial f}{\partial z} \end{bmatrix} = \begin{bmatrix} 2x \\ 2y \\ 2z \end{bmatrix} = 2\mathbf{p}$$

- Normalize $\mathbf{n}_0/|\mathbf{n}_0| = 2\mathbf{p}/2 = \mathbf{p}$

Angle of Reflection

- Perfect reflection: angle of incident equals angle of reflection
- Also: \mathbf{l} , \mathbf{n} , and \mathbf{r} lie in the same plane
- Assume $|\mathbf{l}| = |\mathbf{n}| = 1$, guarantee $|\mathbf{r}| = 1$

$$\mathbf{l} \cdot \mathbf{n} = \cos \theta = \mathbf{n} \cdot \mathbf{r}$$

$$\mathbf{r} = \alpha \mathbf{l} + \beta \mathbf{n} \quad \text{Solution: } \alpha = -1 \text{ and } \beta = 2(\mathbf{l} \cdot \mathbf{n})$$

$$\mathbf{r} = 2(\mathbf{l} \cdot \mathbf{n})\mathbf{n} - \mathbf{l}$$

Perhaps easier geometrically

Summary: Normal Vectors

- Critical for Phong model (diffuse and specular)
- Must calculate accurately (even in OpenGL)
- Pitfalls
 - Not unit length
 - How to set at surface boundary?
- Omitted
 - Refraction of transmitted light (Snell's law)
 - Halfway vector (yet another optimization)

Summary

- Light Sources
- Phong Illumination Model
- Normal Vectors
