## Abstract

The agile methods, such as Scrum and Extreme Programming (XP), have been a topic of much discussion in the software community over the last few years. While the proponents of the agile methods have articulated convincing arguments for their methods, usually within a context of small-to-medium size projects with significant requirements volatility, opponents have expressed serious concerns about the appropriateness and effectiveness of the methods. The research project described in this report is three-pronged effort to investigate the issues associated with Scrum adoption: the practices that characterize the Scrum method, barriers and enablers for successful adoption of Scrum, and the perceived value of Scrum. The objective of this research is to better understand the barriers to adoption and the leverage points that might encourage Scrum to be more widely and efficiently deployed.

**Keywords:** agile methods, change management, innovation, methodology, Scrum, software process, technology adoption, Total Quality Management, TQM

**Acknowledgements:** Thanks to the Scrum Alliance for their support of this research. Thanks also to colleagues who have commented on various drafts of this report, who include Karthik Dinakar, Scott Duncan, Javier Garz as, Ken Schwaber, Jeff Sutherland, and Bas Vodde.

## INTRODUCTION

This report describes an empirical software engineering research project into Scrum adoption. To set the context, the practices that characterize the Scrum method will be stated, along with common variants and tailorings. Potential barriers and enablers of successful technology adoption will be considered to identify what issues might be of interest in the case of Scrum. Software organizations will then be surveyed to identify whether they have considered agile methods such as Scrum, where they might be in the adoption process, and the factors affecting Scrum adoption.

Authorities from the Scrum community, e.g., Schwaber and Sutherland, were consulted to identify what is, and is not, a reasonable tailoring of Scrum. Before we can investigate the factors associated with Scrum adoption, we must be sure that we are considering a legitimate Scrum implementation. Some interesting questions about the Scrum method itself include:

- What are the critical Scrum practices to consider?
- What variations on each of the Scrum practices occur in projects?
- What tailorings are legitimate variations that a project can use and be considered as following the Scrum method?

Organizations that have adopted, or are in the process of adopting, Scrum will be surveyed to identify which Scrum practices, or variants thereof, they have implemented and the perceived value of the method/practices. For those choosing whether to adopt Scrum, understanding the benefits is crucial to the decision. Formal cost/benefit analyses, however, are rarely performed by software organizations (high maturity organizations as rated against the Software CMM or CMM Integration are likely to be exceptions). While objective measures of cost and benefit would be preferred, and will be collected to the degree available, rigorous measures of value are frequently lacking in industry projects, so this first round of research will be based on the perception of value.

The survey will address how these organizations define success and how well Scrum supports projects in being successful. A prerequisite to investigating value is understanding what success means in a specific context. In some cases, success is driven by cost and schedule predictability; for example, in government contracting, predictability and operational excellence are highly valued. In some cases, success is based on functionality delivered and the relationship of that functionality to business objectives. Building a mutually beneficial relationship with the customer can also be considered a measure of success. Understanding the business context will clarify how Scrum supports achieving successful projects in that environment. Some of the interesting questions about what success means for a Scrum project include:

- How is success determined for the project?
- What practices are perceived to work well or badly on Scrum projects?
- What measures of success do Scrum projects use (if any) for the method itself?
- How successful are Scrum projects in terms of their measures of success?

The survey will also identify what factors have influenced the adoption of Scrum. Many sources can be used to identify potential factors, including those affecting the diffusion of innovations, those affecting the marketing of new technologies and products, and those factors that influence the success of software process improvement efforts. Although there is great overlap in the

concerns of these different research areas, each adds a unique perspective that may enlighten the research. Some of the interesting questions about factors affecting Scrum adoption include:

- What external factors, e.g., access to user groups, affect Scrum adoption?
- What internal factors, e.g., training, affect Scrum adoption?

In this document we provide a brief overview of each of the topics we wish to investigate in this research, followed by an identification of the specific items that we might wish to investigate in the context of Scrum adoption. The overviews identify important attributes of the topics but are not comprehensive descriptions; similarly the specific items to investigate filter out many important attributes to focus on particularly relevant information. We anticipate that this initial round of survey-based research will identify a number of questions worthy of further investigation. We hope that some of the organizations involved will consider participating in a more rigorous set of case studies, but that investigation is not considered in this report.

This research will not address criticisms of the agile methods. While the proponents of the agile methods have articulated convincing arguments for their methods, usually within a context of small-to-medium size projects with significant requirements volatility, opponents have expressed serious concerns about the appropriateness and effectiveness of the methods. While Extreme Programming has been the focus of many of these concerns [Keefer03, Stephens03], general criticisms of agile methods include:

- agile methods may not accommodate the working style of the organization's best programmers [Skowronski04],
- there may be a culture clash between the customer's way of doing things and the agile approach [Paulk02],
- agile projects require "premium" or "superbly trained" people [DeMarco02], and
- agile methods legitimize hacker behavior [Rakitin01].

Boehm suggests that "both agile and plan-driven approaches have a responsible center and over-interpreting radical fringes" [Boehm02]. A thoughtful and informed choice of what methods are appropriate for a given project context is needed [Anderson04, Boehm04, Larman04]. This research will investigate some of the factors associated with the success (or failure) of Scrum projects, which may touch on some of these issues, but the focus of the research is not to rebut such criticisms.

The following analysis of agile methods in general, Scrum, good software engineering practices, and technology adoption factors identify many potential topics to explore. To build a usable survey, however, we need to constrain the number of issues to be explored. Factors raised in multiple contexts are the ones most likely to add value when included in the survey.

Other similar surveys include those of Ambler [Ambler11] and Kongyai and Lai [Kongyai11].

## ENGINEERING AND MANAGEMENT PRACTICES

Stating the practices that characterize the Scrum agile method is challenging because Scrum is not a software engineering or development methodology in a strict sense, although it could be described as a project management methodology. It is more of a philosophy or set of values that defines a culture of empowerment and participation within the team and of collaboration and transparency with the customer. Still, it can be characterized by a relatively small set of practices and roles originally established by Ken Schwaber and Jeff Sutherland, but these practices must be interpreted in light of agile values and principles. Some of the practices described in this section are not universally considered part of Scrum and are noted as appropriate.

Elaborating this point, Schwaber<sup>1</sup> commented:

Scrum is a tool, a framework, that can be used to build complex products. It does not prescribe any of the common engineering, people, risk management, or other practices. For instance, it doesn't say the team has to be co-located.

What Scrum does provide is feedback so that someone using Scrum can improve the results. For instance, if someone wants productivity and quality and can have a co-located team, Scrum will point this out. If the person starts with a dispersed team and compares its productivity to another co-located team, conclusions can be reached. An intelligent person would then change (continuous process improvement).

So using Scrum correctly means following all of its rules, which expose everything (transparently) for inspection and adaptation.

An intelligent person would then inspect what Scrum is making transparent and make changes to optimize the results. Presumably, the changes are cost justified.

Someone can use Scrum perfectly and ignore what is made transparent.

Someone can use Scrum imperfectly and act on some of the things that have been made transparent.

Someone who uses Scrum perfectly and acts more intelligently than anyone else on what has been made transparent will out-compete anyone else.

Since Scrum does not explicitly address engineering practices, it is desirable to consider non-Scrum practices that may be tightly linked to Scrum success. For example, test-driven development is frequently advocated for agile projects but is not an explicit Scrum practice. Other methods can act as a source of potential practices that may influence the success of Scrum, because Scrum is frequently implemented in conjunction with methods such as Extreme Programming. Cockburn characterizes the sweet spots for agile projects as two to eight people in one room, onsite usage experts, one-month increments, fully automated regression tests, and experienced developers [Cockburn02]. High requirements volatility is usually assumed for agile projects.

---

<sup>1</sup> K. Schwaber, email to Mark Paulk entitled "Re: a start on identifying survey topics," 27 April 2009.

## Scrum Practices and Roles

Schwaber's two books [Schwaber02, Schwaber04] can be considered the definitive statements of what Scrum is, although the Scrum Alliance published a "Scrum Guide" that may be considered the formal definition of the method [SA09]. Sutherland and Vodde created the Nokia Test to assess the status of teams claiming to use Scrum [Sutherland08]. Silver, another Scrum Alliance member, has also identified crucial characteristics and practices for Scrum [Silver07]. These descriptions of Scrum and its practices are elaborated and clarified in various reports and training, as well as related books [Cohn05, Larman08]. The following brief description of Scrum practices and roles highlights the specific aspects of Scrum that we may wish to investigate to verify that a Scrum implementation is a valid one.

In many cases Scrum is adopted as a whole with little change, but in some cases it is adopted in a "tailored" form. This tailoring may, or may not, represent a reasonable adaptation of the original method. Inappropriate Scrum variations are colloquially known as "ScrumButs." Thus the perceived need for the Nokia Test. It is therefore necessary to investigate the implementation to determine whether a failed Scrum implementation truly reflects the method or an inappropriate and ineffective understanding of what Scrum is. It seems likely that Scrum is a "bundle" of knowledge that is best adopted as a whole [MacDuffie95, Pil96]; piecemeal adoption of Scrum practices is unlikely to achieve the emergent behaviors and benefits of the method.

Scrum is frequently described in terms of

- three roles: ScrumMaster, Product Owner, and Development Team;
- three ceremonies: Sprint Planning Meeting, Daily Scrum Meeting, and Sprint Review Meeting; and
- three artifacts: Product Backlog, Sprint Backlog, and Burndown Chart.

The ScrumMaster is the specific individual responsible for ensuring that Scrum values, practices and rules are enacted and enforced. Some would characterize the ScrumMaster as the project manager who leads by coaching, teaching and supporting the Team rather than directing and controlling. Vodde commented, "A ScrumMaster is not a project manager. The project manager role within Scrum ceases to exist as its responsibilities are moved to the other Scrum roles."<sup>2</sup> Some Scrum projects are reported to have both a ScrumMaster and a project manager (and larger projects using a Scrum of Scrums approach might have a program manager working with multiple ScrumMasters).

The Product Owner is the specific individual responsible for managing and controlling the Product Backlog. The Product Owner sets the priority for each item in the Product Backlog. The Product Owner may represent multiple customer constituencies but has the responsibility and authority to reconcile conflicting requirements and determine the business value associated with each item in the Product Backlog.

The Development Team is typically seven people, plus or minus two. Teams are cross-functional, having all the skills needed to create an increment.

---

<sup>2</sup> B. Vodde, email to Mark Paulk entitled "Re: empirical research into Scrum adoption," 20 May 2009.

A Sprint is one iteration of a month or less that is of consistent length throughout a development effort. Only the Product Owner has the authority to cancel the Sprint. Sutherland and Vodde suggest that Sprints may be 2-6 weeks long.

The Sprint Planning Meeting is when the iteration is planned. It is time boxed to eight hours (for a one month Sprint) and has two parts: determining what will be done in the Sprint and how the Team is going to build the product increment during the Sprint.

The Daily Scrum Meeting is a time-boxed, 15-minute meeting used to inspect progress toward the Sprint goal and to make adaptations that optimize the value of the next workday. During the meeting, each Team member explains:

- 1) What he or she has done since the last Daily Scrum.
- 2) What he or she is going to do before the next Daily Scrum.
- 3) What obstacles are in his or her way.

The Sprint Review Meeting is a four-hour time-boxed meeting (for one-month Sprints) that is held at the end of a Sprint where the Team presents the functionality done in the iteration to the Product Owner and other stakeholders. The Team demonstrates and discusses the work done in the Sprint.

The Product Backlog lists the requirements for the product being developed. It is the master list of all functionality desired in the product, and each item in the Product Backlog has a description, a priority and an estimate of the effort needed to complete it.

The Sprint Backlog is an output of the Sprint Planning Meeting. It consists of the tasks for the Sprint derived from the Product Backlog. “Done” defines what the Team means when they commit to “doing” a Product Backlog item in a Sprint. A completely “done” increment includes all of the analysis, design, refactoring, programming, documentation and testing for the increment and all Product Backlog items in the increment.

A Burndown Chart graphs the estimated work remaining (measured in story points) against time. The Sprint Backlog Burndown is a graph of the amount of Sprint Backlog work remaining in a Sprint against time in the Sprint. The Release Burndown graph records the sum of remaining Product Backlog estimated effort against time.

A number of other ceremonies and artifacts are usually included in Scrum.

The Release Plan describes the goal of the release, the highest priority items in the Product Backlog, the major risks, and the overall features and functionality that the release will contain. It establishes a probable delivery date and cost, assuming that nothing changes. In reviewing a draft of this report, Vodde commented that Scrum only talks about Release Planning rather than a Release Plan. He suggested that a Release Plan is usually just a prioritized, roughly estimated Product Backlog, with stories roughly assigned to the next few iterations. A Release Plan is described in several Scrum descriptions [SA09, Cohn05], including the Nokia Test written by Sutherland and Vodde [Sutherland08], but not all [Schwaber02, Schwaber04, Silver07].

The Sprint Retrospective meeting is a three hour, time-boxed meeting (for one-month Sprints) held after the Sprint Review and prior to the next Sprint Planning meeting where the Team discusses what went well in the last Sprint and what can be improved for the next Sprint.

Scrum projects are typically small to medium sized, but large Scrum projects have been reported. These are typically organized as a “Scrum of Scrums” [Schwaber04]. Scrum has also been adopted at the enterprise level [Schwaber07]. Agile methods in general are assumed to be geographically co-located, but distributed (virtual) teams have been described [Ramesh06, Sutherland07, Sutherland09], although large and distributed projects are quite different from the environment assumed for agile methods in general.

From the perspective of this research, this suggests that the following are of interest:

- Scrum team size
- Product size (LOC, function points, user stories, etc.)
- Cross-functionality of the team (generalists vs specialists)
- Scrum roles (plus variants such as project manager and business analyst)
- Division of concerns in Sprint planning (Product Owner role in setting business priority vs team role in estimating effort)
- Sprints (length)
- Done defined
- Daily Scrum Meetings (frequency)
- Sprint Review Meetings
- Sprint Retrospective Meetings (process improvement)
- Release Plans

## Other Engineering Practices

High requirements volatility is usually assumed for agile projects. Cockburn characterizes the sweet spots for agile projects as two to eight people in one room, onsite usage experts, one-month increments, fully automated regression tests, and experienced developers [Cockburn02].

Probably the two most popular agile methods are Scrum and Extreme Programming (XP). Beck described in terms of twelve practices in the first edition of his book *Extreme Programming Explained: Embrace Change* [Beck99]:

- Planning game
- Metaphor
- Testing (including test-driven development and customer tests)
- Pair programming
- Continuous integration
- On-site customer
- Small releases
- Simple design
- Refactoring (described as design improvement by some)
- Collective (code) ownership
- 40-hour week (later described as sustainable pace)
- Coding standard

In the second edition [Beck04], XP is described in terms of primary practices:

- Sit together
- Informative workspace
- Pair programming
- Weekly cycle
- Slack
- Whole team
- Energized work
- Stories
- Quarterly cycle
- Ten-minute build

- Continuous integration
- Incremental design
- Test-first programming

and corollary practices:

- Real customer involvement
- Team continuity
- Root-cause analysis
- Code and tests
- Daily deployment
- Pay-per-use
- Incremental deployment
- Shrinking teams
- Shared code
- Single code base
- Negotiated scope contract

Combined XP and Scrum methods are popular hybrid agile methods. XP practices that may be particularly pertinent to successful Scrum adoption include test-driven development [Erdogmus05, Kniberg07, Williams03], refactoring [Fowler99], pair programming [Williams02], and sustainable pace [DeMarco01, Goldratt97].

Stephens and Rosenberg discuss a number of concerns about XP in their book *Extreme Programming Refactored* [Stephens03]. Among their concerns are the potential for continuous integration to become occasional integration, the customer not to be available as needed, and teams to not have the generalist skills and competence necessary to do the work. These concerns are valid for other agile methods as well.

Cunningham coined the concept of technical debt: shipping first-time code is like going into debt. A little debt speeds development; the danger occurs when the debt is not repaid. Every minute spent on not-quite-right code counts as interest on that debt [Cunningham92].

Risk management is fundamental to successful software project management [Boehm91, Charette96]. Boehm identifies a set of common software project risks that can act as a starting point:

- Personnel shortfalls
- Developing the wrong functions and properties
- Gold-plating
- Shortfalls in externally furnished components
- Real-time performance shortfalls
- Unrealistic schedules and budgets
- Developing the wrong user interface
- Continuing stream of requirements changes
- Shortfalls in externally performed tasks
- Straining computer science capabilities

Many of the practices in the agile methods are mechanisms for managing risks effectively, e.g., one-month iterations help manage the risk of requirements volatility. While many of these risks, such as a continuing stream of requirements changes, are intrinsically addressed in the agile methods, some, such as shortfalls in externally furnished components or externally performed tasks, can still be concerns. A potential good management practice is identifying and monitoring a set of “top-10” risks.

Similarly, concurrent engineering (also known as integrated process and product development) [Blackburn96, Smith97], is another well-known technique that the agile methods typically address. Cross-functional teams, a focus on the customer, and the use of lead time as a source of competitive advantage are intrinsic to the agile methods, therefore agile methods can be

considered a form of concurrent engineering with the caveat that all the needed skills are represented on the Development Team.

Boehm and Turner identified five critical factors in determining whether agile methods or a plan-driven method was likely to be more suitable for a project: size, criticality, dynamism, personnel, and culture [Boehm04]. Relying on tacit knowledge makes agile methods suitable for small teams but limits scalability. Agile methods may be inappropriate for life-critical and essential moneys projects to the degree they oversimplify design and lack documentation. Agile methods are designed for highly dynamic environments where simple design and refactoring can excel. In general, agile methods require competent people throughout their life. Agile methods are well adapted for cultures with many degrees of freedom.

From the perspective of this research, this suggests that the following are of interest:

- Scrum team size
- Team co-location
- Sustainable pace
- Product size (LOC, function points, user stories, etc.)
- Criticality of product (life-critical, essential moneys, etc.)
- Requirements volatility
- Cross-functionality of the team (generalists vs specialists)
- Experience / competence of team members
- Simple design
- Refactoring
- Technical debt
- Architecture
- Compatibility of organizational culture with Scrum culture
- Risk management
- Customer / Product Owner availability
- Continual integration
- Automated test tools
- Test-driven development
- Pair programming
- Externally-provided software, hardware, and services
- Meeting performance requirements

## **The Agile Culture**

As Schwaber commented, Scrum and the other agile methods should not be viewed as a collection of practices, but rather as a culture or a set of values. Most of the agile gurus emphasize the cultural aspect of agility over a mechanistic set of practices.

From an empirical research perspective, this poses a challenge. If we cannot capture an understanding of what an agile project is by asking about what they do, then how can we operationally define in a repeatable way what “agile” or “Scrum” means? After all, if an iteration can be six months, so long as it captures the agile values (in some sense), can one make a meaningful distinction between agile and traditional waterfall methods? This extreme

interpretation of what the experts say, however, arguably makes the wrong emphasis. A more appropriate interpretation of this position is that a project can implement all of the agile practices it likes – if it does not adopt the agile values, those practices will become an ineffective façade.

Cohn emphasizes that team and project context trump all other considerations, therefore instead of best practices, what we need to know are good practices and the contexts in which they are successful [Kniberg07]. We might infer that, even if a practice is not “agile” (e.g., six-month iterations), it may be appropriate for the team and project context. We will therefore attempt to probe into agile practices while retaining a sensitivity to agile culture that may spark additional research in the future.

One statement of the underlying principles of agile methods was published in association with the Agile Manifesto. The twelve principles<sup>3</sup> are:

1. Our highest priority is to satisfy the customer through early and continuous delivery of valuable software.
2. Welcome changing requirements, even late in development. Agile processes harness change for the customer's competitive advantage.
3. Deliver working software frequently, from a couple of weeks to a couple of months, with a preference to the shorter timescale.
4. Business people and developers must work together daily throughout the project.
5. Build projects around motivated individuals. Give them the environment and support they need, and trust them to get the job done.
6. The most efficient and effective method of conveying information to and within a development team is face-to-face conversation.
7. Working software is the primary measure of progress.
8. Agile processes promote sustainable development. The sponsors, developers, and users should be able to maintain a constant pace indefinitely.
9. Continuous attention to technical excellence and good design enhances agility.
10. Simplicity – the art of maximizing the amount of work not done – is essential.
11. The best architectures, requirements, and designs emerge from self-organizing teams.
12. At regular intervals, the team reflects on how to become more effective, then tunes and adjusts its behavior accordingly.

From the perspective of this research, this suggests that the following are of interest:

- Agile “values”

---

<sup>3</sup> “Principles Behind the Agile Manifesto,” <URL: <http://www.agilemanifesto.org/principles.html>>, visited 16 July 2009.

- Customer satisfaction
- Customer / Product Owner availability
- Requirements volatility
- Sprints (length)
- Simple design
- Refactoring
- Technical debt
- Architecture
- (De)emphasis of documentation
- Sustainable pace
- Self-organizing teams
- Cross-functionality of the team (generalists vs specialists)
- Sprint Retrospective Meetings (process improvement)
- Work environment
- Continual integration
- Automated test tools
- Externally-provided software, hardware, and services

## **FACTORS AFFECTING ADOPTION SUCCESS**

Organizations that have adopted, or are in the process of adopting, Scrum will be surveyed to identify what factors affected adoption and the perceived value of the method/practices. This includes those factors that determine what “success” means to the organization and those that affect technology adoption.

### **Project Success Dimensions**

Shenhar, Levy, and Dvir identified four underlying dimensions for project success [Shenhar97]:

- customer satisfaction, i.e., meeting requirements, fulfilling customer needs
- budget and schedule, i.e., meeting time and budget goals
- business success, i.e., the level of commercial success or market share
- future potential, i.e., opening new markets, developing new technologies

The traditional dimension of meeting time, budget, and performance goals is not really a homogenous dimension, since meeting project resource constraints (time and budget) is one thing, while meeting requirements is another. Poor requirements may result in dissatisfied customers even when specifications are fully met.

During project execution, project managers focus on please prospective customers, meeting time and budget goals, and succeeding commercially (to some extent). After the project is fielded, success is determined more by the impact of the project on the future of the organization. It may be that Microsoft has never had a project come in on budget or on schedule, but they are without question a highly successful company.

In general, agile methods seem to focus well on customer satisfaction and business success. Future potential depends on the organizational reason for initiating the project, so may be an issue outside of project scope. Budget and schedule issues would seem to be secondary, subordinate to customer satisfaction and business success, although important to the degree that the customer and the business prioritize cost and schedule issues.

From the perspective of this research, this suggests that the tradeoff between customer satisfaction, budget, schedule, business success, and future potential is of interest. While all may be considered important, one is likely the primary driver in making tradeoff decisions.

### **Value Disciplines**

Treacy and Wiersma identified three value disciplines that companies can follow to be the best in their markets [Treacy97]. These are driven by quite different strategies in satisfying (or delighting) customers; for all three, customer value is the ultimate measure of one’s work performance, and improving value is the measure of one’s success. The three value disciplines are operational excellence, product leadership, and customer intimacy.

Operationally excellent companies provide middle-of-the-market products at the best price with the least inconvenience – the best total cost for their customers. They use standardized assets and efficient operating procedures and reject variety because it burdens the business with cost. They have three advantages: (1) focus, hassle-free basic service as a key part of their value proposition; (2) efficient, zero-defect service; and (3) use of information technology to redesign basic service tasks. Operationally excellent companies live or die by process improvement, governed generally by the principles of total quality management.

Product leaders offer products that push performance boundaries. They offer the best product, and competition is about product performance. Product leaders avoid bureaucracy at all costs. Success is driven by the extraordinary talents of key individuals who develop and market breakthrough after breakthrough. Operating procedures and processes are designed to play into the drivers of individual behavior, which include a thirst for problem-solving and a distaste for bureaucracy. Product leaders create flexible organizational structures and robust processes that enable people to flex their minds without creating disruption. They provide efficient coordination, while accommodating inventiveness and discipline. Product leaders create business structures that don't oppress and stress procedures where it pays the biggest dividend, typically during the final leg of the product development effort.

Customer-intimate companies focus on delivering what specific customers want – the best total solution. They do not pursue one-time transactions; they cultivate relationships. They prefer steady, controlled, incremental evolution of product coupled with expertise that leads the clients through changes in their application and management.

Each value discipline requires a company to emphasize different processes, to create different business structures, and to gear management systems differently. Treacy and Wiersema argue that, if you decide to play an average game, to dabble in all areas, you can't expect to become a market leader. They also argue that you must focus on a specific value discipline while maintaining threshold standards on the other dimensions of value.

Agile methods such as Scrum are well suited to the needs of product-leader and customer-intimate companies. They are useful to operationally excellent companies, but there is more likely to be a culture clash with the existing practices designed to focus on operational excellence. (Best practice frameworks such as CMMI for Development are focused on operational excellence issues.)

From the perspective of this research, this suggests that which market discipline is preeminent for the organization implementing Scrum is of interest.

## **Diffusion of Innovation Factors**

Change is not necessarily for the better. Fads and fashions drive change based on imitating other, successful organizations [Abrahamson91, DiMaggio83]. This kind of diffusion occurs when organizations have unclear goals and high uncertainty about the technical efficiency of the innovations they are considering. Organizations that lack a good understanding of the underlying culture of Scrum may adopt an ineffective variant of the method, thus the need to understand more about how Scrum has been implemented before drawing conclusions about the adoption of the method. If we can assume that adoption is based on rational choice, then innovations such as

Scrum diffuse when they benefit organizations adopting them, and they disappear when they do not.

Focusing on a rational and efficient-choice style of adoption, the diffusion of innovation literature identifies five factors that affect the successful adoption of an innovation [Rogers83]:

- perceived relative advantage - the extent to which adopters believe the innovation is better than current practice;
- compatibility - the degree to which an innovation is perceived by the adopter as consistent with their needs, values, and experiences;
- simplicity - the degree to which the innovation is perceived as understandable and implementable;
- trialability - the degree to which an innovation can be experimented with on a limited basis; and
- observability - the degree to which an innovation and its benefits can be observed by the potential adopter.

From the perspective of this research, this suggests that the following are of interest:

- Perceived relative advantage of Scrum over other methods
- Compatibility of organizational culture with Scrum culture
- Understandability of Scrum – need for training, consulting, and coaching support
- Specific business problems addressed by Scrum
- Measurable (objective) benefit from Scrum

## **Adopter Communities and the Chasm**

A common model for characterizing the classes of people involved with technology adoption is that they can be listed as innovators (techies), early adopters (visionaries), early majority (pragmatists), late majority (conservatives), and laggards (skeptics) [Rogers03]. Moore extends this by identifying a “chasm” that separates early adopters and the early majority; a gap between two fundamentally separate phases in the development of a high-tech market [Moore91]. The early phase builds from a few, highly visible, visionary customers, but transitioning to the mainstream phase, where the buying decisions fall predominantly to pragmatists, is a major challenge. The key to Moore’s insight is characterizing the differences between these communities and how to proactively deal with them.

The “chasm” has implications for adoption of models and standards, since a number of enabling mechanisms expedite adoption, including the existence of:

- ownership: agencies responsible for developing and maintaining the best practice framework
- user groups
- conferences and publications, including case studies of adoption and improvement
- training materials: books, continuing education courses, videos
- Web page: for the sponsor of the work and supporting materials
- penetration: breadth of adoption (world-wide vs national or regional)

It appears that Scrum has moved into early majority adoption phase around the world. From the perspective of this research, this suggests that the following are of interest:

- Awareness of agencies supporting Scrum, such as the Scrum Alliance
- Awareness of local Scrum user groups
- Awareness of Scrum on-line discussion groups
- Awareness of Scrum and agile conferences
- Training (professional education, Webinars) on Scrum
- Consulting / coaching support for Scrum piloting
- Awareness of publications (papers, books, Websites) on Scrum

## **The Assimilation Gap**

Fichman and Kemerer take a slightly different perspective by examining the “assimilation gap” between a new technology being acquired by an organization, the traditional mechanism for measuring adoption, and its actual deployment and use [Fichman93; Fichman95]. Many researchers treat the acquisition of a technology as the adoption event, yet the failure to address the actual deployment makes a critical assumption about the last stages of the standard technology adoption curve.

Fichman and Kemerer point out that widespread acquisition of a technology is not necessarily followed by widespread deployment and use, which they characterize as an “assimilation gap.” Traditionally, innovation attributes such as relative advantage, complexity, and compatibility are viewed as the determinants of the rate and level of diffusion. Fichman and Kemerer propose that acquisition and deployment have different drivers, even though they are related processes. Acquisition is driven by the expectation of future benefits owing to increasing returns, but knowledge barriers impede deployment.

To address the assimilation gap via organizational learning (or process management) implies that the organization recognizes the difference between acquiring and deploying a technology and is proactive in tracking and addressing deployment issues. This means understanding the factors influencing returns to adoption (such as network externalities, learning-by-doing, and technological interrelatedness) and knowledge barriers (such as complexity and scaling).

From the perspective of this research, this suggests that the following are of interest:

- Awareness of agencies supporting Scrum, such as the Scrum Alliance
- Awareness of local Scrum user groups
- Awareness of Scrum on-line discussion groups
- Awareness of Scrum and agile conferences
- Training (professional education, Webinars) on Scrum
- Consulting / coaching support for Scrum piloting
- Piloting of Scrum
- Awareness of publications (papers, books, Websites) on Scrum
- Work environment

## Daghfous and White Innovation Analysis

Daghfous and White integrated a number of time-based approaches to characterizing the process of innovation that consider product and process evolution and marketing [Daghfous91]. They add an information axis and a focus on how information interacts with the demand and supply axes. Their innovation analysis model has three dimensions – product/process, application linkage, and information.

The product/process axis, also known as the supply axis, is the axis along which events proceed technically, from initial invention to successful innovation. The applications linkage axis, also known as the demand axis, is the axis along which those events that define markets proceed, from initial definition of concept value to successful application of the innovative product. The information axis deals with the transformation of uncertainty and ignorance into precise knowledge. *Uncertainty* means that the information does not exist to remove variance of expectations. *Ignorance* means the information is known or accessible elsewhere, but the innovator is oblivious and thus at competitive disadvantage.

Managerial decisions regarding innovation are dominated by (the lack of) information. Lack of information is a major inhibitor to innovation, and addressing this lack is a direct consequence of innovation – although resolving uncertainty and ignorance requires different approaches. Information gathering along the product/process axis usually results in removing ignorance. Information gathering along the application linkage axis usually results in removing uncertainty. It can be assumed that once information is learned, it will not be forgotten. The ultimate objective, or “bulls-eye,” for an innovation is continuing market evolution under precise knowledge, with optimum products from optimum processes satisfying optimum demand. The sequence, if not the timing, of events is predictable using the Daghfous & White model.

To manage innovations that may be adopted externally via organizational learning (or process management) implies that the organization recognizes the importance of the information axis and how it impacts the other axes. This means analyzing exactly where a technology (or product) is on the process/product and application linkage axes.

From the perspective of this research, this suggests that the following are of interest:

- Awareness of agencies supporting Scrum, such as the Scrum Alliance
- Awareness of local Scrum user groups
- Awareness of Scrum on-line discussion groups
- Awareness of Scrum and agile conferences
- Training (professional education, Webinars) on Scrum
- Consulting / coaching support for Scrum piloting
- Awareness of publications (papers, books, Websites) on Scrum
- Piloting of Scrum
- Measurable (objective) benefit from Scrum

## Successful Change Programs

Beer, Eisenstat, and Spector characterize company-wide change programs as the “fallacy of programmatic change,” suggesting that successful transformations usually start at the periphery

of the company to solve concrete business problems [Beer 1990]. They identify six steps on the critical path to successful change:

- Mobilize commitment to change through joint diagnosis of business problems.
- Develop a shared vision of how to organize and manage for competitiveness. They suggest that the root of the problems faced by the organization are functional and hierarchical barriers to sharing information and solving problems.
- Foster consensus for the new vision, competence to enact it, and cohesion to move it along.
- Spread revitalization to all departments without pushing it from the top. They suggest that it is better to let each department reinvent the wheel if necessary in finding its own way to the new organization.
- Institutionalize revitalization through formal policies, systems, and structures. Mechanisms such as policies are important so the process continues even after the sponsoring managers of change have moved on to other responsibilities.
- Monitor and adjust strategies in response to problems in the revitalization process. They encourage creating a learning organization to deal with the changing competitive environment.

From the perspective of this research, this suggests that the following are of interest:

- Specific business problems addressed by Scrum
- Compatibility of organizational culture with Scrum culture
- Buy-in for Scrum at the local (project / team) level
- Organizational support for Scrum
- Piloting of Scrum
- Process improvement context for Scrum adoption and adaptation

## **Competency Traps**

Pil and MacDuffie argue that radical changes, including fundamental shifts in technologies and methodologies, can be competence destroying [Pil96]. This can lead to “competency traps,” where organizations maintain inferior routines they have had favorable experience with in the past. Thus superior practices that do not yield immediate results face a high risk of not being retained. Oddly enough, the cost of change is less for poorly performing organizations.

Pil and MacDuffie identified two major types of disruptions in assembly plants that could result in unfreezing the current way of doing things: major product changeovers and significant new additions to the plants.

High-involvement work practices may represent “competence-destroying” change, which is difficult to implement, and may lead to worsened performance in the short term (and thus *not* an economically rational choice for individual managers held accountable for short-term results). These practices may also have a less favorable impact on performance if they are not given adequate time to develop. For both of these reasons, firms may be discouraged from making changes in work practices (particularly change involving “bundles” of interdependent practices rather than individual practices), or from continuing with change efforts beyond an initial trial period.

Given these impediments to change, Pil and MacDuffie argue that there are three key factors at the plant or establishment level that drive the adoption of new work practices (and “bundles” of practices): (1) the level of complementary organizational practices and technologies that would increase the *benefit* from the new practices, (2) the performance levels the organization is achieving with its current practices, and (3) organizational characteristics or actions that alter the *cost* of introducing the new practices.

From the perspective of this research, this suggests that the following are of interest:

- Specific business problems addressed by Scrum
- Measurable (objective) benefit from Scrum
- Compatibility of organizational culture with Scrum culture

## Process Improvement Factors

Change management covers a broad range of adoption issues. Process improvement addresses a more focused set of issues more directly related to software engineering methodologies, which may provide additional factors to consider for Scrum adoption. Some have observed that the majority of improvement programs fail, with reports of 80% failures being fairly typical [Goodman96] and indications that fewer than 10% of the Fortune 1000 have well-developed TQM programs [Repenning01]. If adoption failures for agile methods are as high, it would perhaps not be surprising.

El Emam, Goldenson, McCurley, and Herbsleb observed that the most important factor in distinguishing between success and failure of software process improvement efforts is the extent to which the organization is focused in its improvement effort, with clearly defined goals and consistent directions set by senior management [Emam98]. Factors that may be worth exploring for Scrum adoption include:

- *Lack of management commitment.* Goodman believes this problem occurs because the people involved in the quality programs talk quality rather than business in terms that managers relate to [Dyba05, Goodman96, Kasse00, Niazi06, Powell95]. Discussing Scrum in engineering terms rather than business concerns could lead to a similar problem.
- *Lack of clearly defined goals.* Goals depend on a clear statement of the desired benefit to be obtained by adopting a new technology, which provides a foundation for measuring progress and determining success [Dyba05, Emam98, Kasse00].
- *Staff inexperience.* The skills needed to solve technical problems can be very different from the skills necessary to successfully manage people [Baddoo03, Goodman96, Kasse00, Niazi06], especially when changing management paradigms from control-oriented approach to an empowered, coaching style.
- *Lack of training.* Investing in the necessary training to enable new methods and techniques to flourish is a common problem [Niazi06, Powell95]. Agile methods such as Scrum require new skills in management, technical, and teamwork areas.

- *The Pilot Syndrome.* The effects of pilots may take many months to assess and any benefits they deliver will be confined to the pilot area and will not impact the overall business [Goodman96]. Management commitment may slip away during the pilot. The delay between investing in improvement activities and reaping the benefits is a general problem with working smarter versus working harder [Repenning01].
- *A lack of measurement.* Evidence-based management supports the adoption of successful new technologies based on objective evidence [Dyba05, Niazi06, Powell95, Rousseau07, Schaffer92]. Agile methods, however, are not known for their use of data in decision making, including quantitative or statistical arguments for why to adopt agile methods.
- *Process versus results orientation.* Arguments in favor of a new technology should be based on the business results obtained to get senior management buy-in [Schaffer92]. This goes back to the definition of success, but observed results are crucial to successful adoption.
- *Commercial pressures.* External pressures, even if perhaps unrealistic, can lead to failure [Baddoo03, Kasse00]. The Product Owner is responsible for prioritizing conflicting requirements, and perhaps even deciding to terminate the project if it cannot meet its business objectives, but it is human nature to succumb to pressure on occasion.
- *Tool support.* While technology is not a silver bullet, it is important to support the efficient adoption of new methods [Kasse00]. Automated regression testing, for example, makes the adoption of agile methods much easier.

From the perspective of this research, this suggests that the following are of interest:

- Specific business problems addressed by Scrum
- Measurable (objective) benefit from Scrum
- Management sponsorship for Scrum piloting and adoption
- Compatibility of organizational culture with Scrum culture
- Training (professional education, Webinars) on Scrum
- Consulting / coaching support for Scrum piloting
- Piloting of Scrum
- Work environment
- Automated test tools
- Consistent implementation of Scrum practices (as selected and adapted for the organization)

## Cultural Issues

For this initial round of research, cultural issues affecting adoption will not be investigated, but they are important factors influencing how people work together, deal with change, and feel about innovation. Some consideration of national and organizational cultures is necessary to understand Scrum implementation and adoption issues, but a full-blown study of cultural factors is beyond the scope of this initial investigation.

Hofstede identified four largely independent dimensions of differences among national value systems [Hofstede96]. These were labeled power distance (power is distributed unequally, status differences), uncertainty avoidance (tolerance for uncertainty and ambiguity), individualism vs. collectivism (interests of the individual vs. interests of the group that individual is a member of), and masculinity vs. femininity (confrontation vs. compromise). A fifth dimension identified later was termed Confucian dynamism (long-term vs. short-term orientation in life and work). We might expect agile methods to flourish in a culture with small power distance, willingness to tolerate ambiguity, willingness to compromise, and a long-term view.

Constantine defined four broad categories of organizational culture [Constantine93, Constantine95]. Closed paradigm organizations are hierarchical. They rely on standards and rules of operation to promote continuity. Random paradigm organizations directed at innovation and change through individual creativity. Open paradigm organizations rely on open communication and consensual decision making. Synchronous paradigm organization use tacit agreement for alignment. Each paradigm has particular strengths, as well as intrinsic weaknesses. For teams, Constantine recommends the structured open team, which is a tight-knit, closely integrated team of professional equals with clear differentiation of functions only as necessary for effective functioning. To avoid problems intrinsic to the consensual decision making, the technical leader is responsible for resolving technical disputes.

There are a number of other national and organizational culture taxonomies that might provide useful insight [Handy91, Schein92], but the Hofstede and Constantine models illustrate the kinds of cultural issues we may consider in future research.

## SURVEY DESIGN

A Web-based survey will be used to solicit information on Scrum implementation and adoption. Web-based surveys are convenient, allow rapid data collection, are cost-effective, allow respondents ample time to consider their responses, can be confidential and secure, and allow the researcher to target specialized populations. They do, however, have some disadvantages [Rea05]:

- The respondents must have access to the Web and be computer literate. For software professionals adopting Scrum this should not be a significant issue.
- Many potential respondents do not respond to e-mail solicitations, leading to low response rates and a potential self-selection bias. It will be necessary to analyze the responses to see if this is a significant issue in the context of the populations targeted for the survey.
- Since there is no interviewer involvement, unclear questions cannot be easily clarified, and respondents may not follow instructions. Potential measures to alleviate this concern include embedding links to definitions and clarifying material in the survey, providing e-mail contacts for questions, and providing comment fields to allow for additional information. The survey will also be reviewed by colleagues at Carnegie Mellon and members of the Scrum Alliance prior to use.

After the Web-based survey responses are analyzed, follow-up interviews to probe specific issues and/or implementations will be scheduled as appropriate. Those interviews are outside the scope of issues described in this report.

The general population targeted by this survey could be considered the universe of software professionals, as well as the customers of software projects and the users of software products. The membership of the Scrum Alliance provides a sample of Certified ScrumMasters and other Scrum roles, but this is not an ideal sample since one of the objectives of this research is to understand the barriers to Scrum adoption. Members of the Scrum Alliance are not representative of the larger population of software professionals since there is a reasonable assumption that they have overcome many of the barriers to adoption that we would like to understand better. The Scrum Alliance sample is useful, but additional samples are needed to address the self-selection bias inherent in membership.

Representatives of the Project Management Institute (PMI) have expressed an interest in supporting this research. PMI membership includes thousands of Certified Project Management Professionals, many of whom manage software projects. A PMI sample would provide a view into organizations that have decided not to adopt Scrum or other agile methods at this time, along with the reasoning behind that decision, along with those who have adopted Scrum or other agile methods with affiliation with the Scrum Alliance.

Another interesting sample is the list of high maturity organizations as measured using the Software Engineering Institute's Capability Maturity Model Integration (CMMI) for Development [Chrissis06]. High maturity organizations should be actively interested in innovative software engineering concepts that can improve performance; agile methods are an increasingly popular, if sometimes controversial, topic within the software community. Surveying high maturity organizations to determine their adoption of agile methods, including Scrum, and their reasons for adopting (or not) will provide the perspective from organizations

that in principle should be near the frontier of adopting effective software engineering innovations, although they may remain in the early (or late) majority in diffusion of innovation terms, depending on their business objectives and environment.

These three communities provide a reasonably comprehensive sample of the overall software community, emphasizing three quite different perspectives on software engineering.

This is an observational study. This kind of survey is intrinsically biased by the nature of the respondents. Those interested in responding are more likely to be favorable to agile methods and Scrum than those who do not respond. As a result, we can consider the results indicative, but not definitive.

## **NEXT STEPS AND FUTURE RESEARCH**

This report describes empirical research into Scrum implementation and adoption that is planned. The next steps are to design the survey instrument, have it reviewed by selected colleagues from academia and members of the Scrum Alliance, administer the survey to the three target groups, analyze the data, and publish the results. Those results may inform subsequent actions by various stakeholders in encouraging and enabling Scrum adoption.

The research begins with a Web-based survey, but follow-up in the form of e-mail, telephone interviews, and on-site discussions may be desirable to clarify the data and expand our insights. These follow-ups may result in case studies of Scrum adoption by specific organizations, but those case studies are potential future research that is outside the scope of this report.

We may reasonably expect this research will spark further questions that may be address via additional surveys. Those surveys are potential future research that is outside the scope of this report.

This research project will focus on industry organizations and projects, but the studio projects for Carnegie Mellon's Masters in Software Engineering (MSE) program offer the opportunity for focused case studies. Whether the insights available from a student context are worth actively pursuing will be discussed with the various stakeholders. Any research conducted in the MSE environment are potential future research that is outside the scope of this report.

## APPENDIX A. SOLICITATION

Greetings,

The 2001 Scrum Adoption Survey is intended to uncover issues related to technology transition of the agile method Scrum. If you work on a software project, we would like to have your input whether you use Scrum or not. If you don't use Scrum, this survey should take less than five minutes to finish. If you do, it should take less than 15 minutes. In return for participating, we will send you an early draft version of the survey results and keep you informed of any publications based on the survey.

Your input will be considered confidential. No individual, project, or organization will be identified in the publications resulting from this survey.

To take the survey, go to <survey URL xxx>. This survey will close on xxx.

For more information on this survey, go to <<http://www.cs.cmu.edu/~mcp/agile/oersa.pdf>>. If you have any questions about this survey, please contact Mark Paulk, [mcp@cs.cmu.edu](mailto:mcp@cs.cmu.edu).

Thank you for your participation,

Mark Paulk

Carnegie Mellon University

## APPENDIX B. THE 2011 SCRUM ADOPTION SURVEY

The following survey should take less than 15 minutes to complete. Depending on the size of your company, the organization name may be an entire company or a business unit within a company (or government agency). Include enough information to clearly identify the organization developing software. No organization, project, or individual will be publicly identified for participating in this survey.

Organization (required):

City (required):

State / Province:

Country (required): (*default "United States"*)

How large is the organization (number of employees)? (*≤25, 26-50, 51-75, 76-100, 101-200, 201-300, 301-500, 501-1000, 1001-2000, >2000*)

What certifications does the organization have (select all that apply)?

- ISO 9001 (*2011, 2010, 2009, 2008, 2007, 2006, 2005, Before 2005*)
- Software CMM or CMMI-DEV level 2 (*2011, 2010, 2009, 2008, 2007, 2006, 2005, Before 2005*)
- Software CMM or CMMI-DEV level 3 (*2011, 2010, 2009, 2008, 2007, 2006, 2005, Before 2005*)
- Software CMM or CMMI-DEV level 4 (*2011, 2010, 2009, 2008, 2007, 2006, 2005, Before 2005*)
- Software CMM or CMMI-DEV level 5 (*2011, 2010, 2009, 2008, 2007, 2006, 2005, Before 2005*)
- Other organizational certifications:

Usage of Scrum by the organization can be described as:

- We never heard of Scrum before
- We are aware that Scrum exists
- We are currently piloting Scrum
- We have piloted Scrum but no decision about adoption has been made
- We are currently deploying Scrum across the organization
- Scrum is one of the standard methods we use
- Scrum is the normal way we build software

What other software engineering methods is the organization using (select all that apply)?

- Extreme Programming (XP)
- Feature Driven Development (FDD)
- Crystal methods, including Crystal Clear
- Unified Process (UP, RUP, AUP, OUP)
- Team Software Process (TSP)
- Other:

Which of the following have you attended (select all that apply)?

- An agile methods presentation
- A Scrum presentation
- An agile methods conference
- A Scrum conference, e.g., a Scrum Gathering
- A local agile methods or Scrum user group
- Other:

*If the usage of Scrum is in the range “never heard” to “aware”, go to “Closing”.*

### *Project Demographics*

Please answer the rest of this survey from the perspective of a specific Scrum project.

Project name (required):

Type of software being developed:

- MIS / business software
- System software
- Commercial shrink-wrap software
- Embedded system software
- Web-based software
- Other:

Industry:

- Government (non-defense)
- Defense
- Aerospace
- Education
- Financial
- Healthcare
- Insurance
- Manufacturing
- Public utilities
- Telecommunications
- Other:

How many Sprints has the Scrum project finished? ( $\leq 3$ , 4-6,  $\geq 7$ )

How many people are on the Development Team? ( $\leq 3$ , 4-6, 7-9, 10-12, 13-15,  $\geq 16$ )

The highest business priority for the project can be described as: (*addressing customer needs, meeting budget / schedule constraints, new features and innovation, unknown*)

Any comments on the project:

## *Scrum Roles*

Which of the following describe the ScrumMaster of the project (select all that apply):

- There is a single ScrumMaster
- There is a project manager who acts as the ScrumMaster
- There is a project manager separate from the ScrumMaster

Which of the following describe the Product Owner (select all that apply):

- There is a single Product Owner who has the authority to set business priorities for the project
- The Product Owner integrates and reconciles the desires of multiple stakeholders
- The Product Owner is co-located with the Development Team

Which of the following describe the Development Team (select all that apply):

- The Development Team is co-located (can easily see and hear colleagues)
- One team member is located at a different geographical location
- The Development Team is distributed across multiple geographical sites (a virtual team)
- Some (more than one) team members are part-time members
- The Development Team estimates the effort, e.g., story points, for items in the Product Backlog
- The Development Team works at a sustainable pace
- Development Team members are generalists who can work on any task

Which of the following describe the training and consulting support available (select all that apply):

- The ScrumMaster has received multiple-day professional education on the ScrumMaster role
- The ScrumMaster is a Certified ScrumMaster
- The Product Owner is a Certified Product Owner
- The Development Team has all the skills needed to do the work
- The Development Team members have received multiple-day professional education on Scrum
- A Scrum coach helps the Development Team on a day-to-day basis
- Consulting support is available to answer questions about the Scrum method

Any comments on Scrum roles:

## *Scrum Process*

Requirements volatility (i.e., new or changed user stories in the Product Backlog) can be described as: (*<1% per month, 1-3% per month, 3-5% per month, 5-10% per month, 10-20% per month, 20-50% per month, >50% per month*)

Sprints can be described as: (*one week, two weeks, 3-4 weeks, one month, 4-6 weeks, >6 weeks, kanban-style continuous workflow, variable length*)

Daily Scrum meetings can be described as: (*held every day, held multiple times per week but not necessarily daily, held as needed, not done*)

Integration and testing of the software can be described as occurring: *(multiple times per day, daily, frequently during the week, weekly, as needed)*

Which of the following accurately describe the Scrum process and software (select all that apply):

- There is a “product vision” that clearly states the business goals and requirements for the product
- There is a requirements specification maintained under change control
- The principle of simple design is used, with design improvement (refactoring) as appropriate
- An architecture has been developed that provides an adequate design context for the work (and it evolves as necessary)
- Technical debt is measured for the project
- There is an appropriate emphasis on documentation
- Pair programming is done
- Test-driven development is done
- Each requirement (user story) is appropriately tested, and the test cases are included in the regression tests (for continuous integration)
- There is a common understanding within the Development Team of what “done” means for the items in the Sprint Backlog
- A Sprint Retrospective Meeting is held at the end of Sprints to identify opportunities for process improvement
- Appropriate and effective tools are available to support the work (e.g., automated test tools)
- Risks are identified for the project and reviewed at the end of each Sprint

The Scrum process is followed: *(Always, Usually, Frequently, Sometimes, Rarely)*

Any comments on the Scrum process:

### *Culture and Value*

Which of the following accurately describe the culture of the project (select all that apply):

- There is an open, cooperative, and collaborative relationship with the customer (Product Owner)
- There is an open, cooperative, and collaborative relationship within the Development Team
- The Development Team is appropriately empowered to do its work
- The Development Team is self-organizing

Relative to other software engineering methods, how does Scrum compare with respect to:

- Quality of the software (*much higher, higher, about the same, lower, much lower, unknown*)
- Cost (*much higher, higher, about the same, lower, much lower, unknown*)
- Meeting schedule expectations (*much higher, higher, about the same, lower, much lower, unknown*)
- Customer satisfaction (*much higher, higher, about the same, lower, much lower, unknown*)

Which of the following accurately describe the Scrum adoption process:

- Senior management actively sponsored the piloting and/or adoption of Scrum
- There is a clear set of business goals to be achieved in adopting Scrum
- Process / product measures have been identified for determining the success of Scrum
- There was a significant culture clash between the old way of building software and Scrum

Any comments on Scrum culture, benefits, or adoption:

*Closing*

Your email address:

What is your role in the organization?

- *Senior management*
- *Process / quality group member*
- *Project manager*
- *Software professional*
- *Business analyst*
- *Marketing / sales*
- *ScrumMaster*
- *Product Owner*
- *Scrum Development Team member*

What certifications do you have (select all that apply)?

- *Certified ScrumMaster*
- *Certified Product Owner*
- *Certified Scrum Developer*
- *Certified Scrum Professional*
- *ASQ Certified Software Quality Engineer*
- *IEEE Certified Software Development Professional*
- *Professional Engineer*
- *Other:*

Thank you for participating in this survey. If you have provided your email address, you will be added to the distribution list for the results of this survey.
