L-8 Wireless

Wireless Intro

- TCP on wireless links
- Wireless MAC
- Assigned reading
 - [BM09] In Defense of Wireless Carrier Sense
 - [BPSK97] A Comparison of Mechanism for Improving TCP Performance over Wireless Links (2 sections)
- Optional
 - [BDS+94] MACAW: A Media Access Protocol for Wireless LAN's

2

Wireless Challenges

- Force us to rethink many assumptions
- Need to share airwaves rather than wire
 - Don't know what hosts are involved
 - Host may not be using same link technology
- Mobility
- Other characteristics of wireless
 - Noisy → lots of losses
 - Slow
 - Interaction of multiple transmitters at receiver
 - Collisions, capture, interference
 - Multipath interference

3

Overview

- **Wireless Background**
 - **Review**
- **Wireless MAC**

 - 802.11
- **Wireless TCP**

4

Transmission Channel Considerations

- Every medium supports transmission in a certain frequency range.
 - Outside this range, effects such as attenuation, .. degrade the signal too much
- Transmission and receive hardware will try to maximize the useful bandwidth in this frequency band.
 - Tradeoffs between cost, distance, bit rate
- As technology improves, these parameters change, even for the same wire.
 - Thanks to our EE friends

5

The Nyquist Limit

- A noiseless channel of width H can at most transmit a binary signal at a rate $2 \times H$.
 - E.g. a 3000 Hz channel can transmit data at a rate of at most 6000 bits/second
 - Assumes binary amplitude encoding

6

Past the Nyquist Limit

- More aggressive encoding can increase the channel bandwidth.
 - Example: modems
 - Same frequency - number of symbols per second
 - Symbols have more possible values

7

Capacity of a Noisy Channel

- Can't add infinite symbols - you have to be able to tell them apart. This is where noise comes in.
- Shannon's theorem:
 - $C = B \times \log(1 + S/N)$
 - C : maximum capacity (bps)
 - B : channel bandwidth (Hz)
 - S/N : signal to noise ratio of the channel
 - Often expressed in decibels (db). $10 \log(S/N)$.
- Example:
 - Local loop bandwidth: 3200 Hz
 - Typical S/N : 1000 (30db)
 - What is the upper limit on capacity?
 - Modems: Teleco internally converts to 56kbit/s digital signal, which sets a limit on B and the S/N .

8

Free Space Loss

$$\text{Loss} = P_t / P_r = (4\pi d)^2 / (G_r G_t \lambda^2)$$

- Loss increases quickly with distance (d^2).
- Need to consider the gain of the antennas at transmitter and receiver.
- Loss depends on frequency: higher loss with higher frequency.
 - But careful: antenna gain depends on frequency too
 - For fixed antenna area, loss decreases with frequency
 - Can cause distortion of signal for wide-band signals

9

Cellular Reuse

- Transmissions decay over distance
 - Spectrum can be reused in different areas
 - Different “LANs”
 - Decay is $1/R^2$ in free space, $1/R^4$ in some situations

10

Multipath Effects

- Receiver receives multiple copies of the signal, each following a different path
- Copies can either strengthen or weaken each other.
 - Depends on whether they are in or out of phase
- Small changes in location can result in big changes in signal strength.
 - Short wavelengths, e.g. 2.4 GHz $\rightarrow$ 12 cm
- Difference in path length can cause inter-symbol interference (ISI).

11

Fading - Example

- Frequency of 910 MHz or wavelength of about 33 cm

12

Overview

- Wireless Background
- **Wireless MAC**
 - **MACAW**
 - 802.11
- Wireless TCP

13

Medium Access Control

- Think back to Ethernet MAC:
 - Wireless is a shared medium
 - Transmitters interfere
 - Need a way to ensure that (usually) only one person talks at a time.
 - Goals: Efficiency, possibly fairness

14

Example MAC Protocols

- Pure ALOHA
 - Transmit whenever a message is ready
 - Retransmit when ACK is not received
- Slotted ALOHA
 - Time is divided into equal time slots
 - Transmit only at the beginning of a time slot
 - Avoid partial collisions
 - Increase delay, and require synchronization
- Carrier Sense Multiple Access (CSMA)
 - Listen before transmit
 - Transmit only when no carrier is detected

15

CSMA/CD Does Not Work

- Carrier sense problems
 - Relevant contention at the **receiver**, not sender
 - Hidden terminal
 - Exposed terminal
- Collision detection problems
 - Hard to build a radio that can transmit and receive at same time

16

20

-
- The diagram shows a sequence of nodes A, B, C, D, E, and F. Nodes B and E are red, while nodes A, C, D, and F are light blue. A large circle encloses nodes B, C, and D. An arrow labeled "DATA" points from node C to node D. This visualizes a data stream where data is processed sequentially, with some nodes (B and E) potentially representing specific events or states within the stream.

21

22

- | Error Rate | RTS-CTS-DATA | RTS-CTS-DATA-ACK |
|------------|--------------|------------------|
| 0 | 40.41 | 36.76 |
| 0.001 | 36.58 | 36.67 |
| 0.01 | 16.65 | 35.52 |
| 0.1 | 2.48 | 9.93 |

-
- Diagram illustrating a scenario where node C hears RTS and DS signals but does not hear CTS from node A.

23

-
- The diagram illustrates the CSMA/CD protocol with four scenarios:
- Successful Transmission:** Station B1 sends frame S1 to station P1. P1 receives it and sends back an ACK. B1's backoff increases.
 - Collision:** Station B1 sends frame S1 to P1. Simultaneously, station P2 sends frame S2 to B2. A collision occurs, indicated by a red 'X'.
 - Retransmission after Collision (B1's perspective):** After the collision, P1 sends a RTS to B1. B1 then retransmits S1 to P1.
 - Retransmission after Collision (P2's perspective):** After the collision, B2 sends a RTS to P2. P2 then retransmits S2 to B2.

24

MACAW: Conclusions

- 8% extra overhead for DS and ACK
- 37% improvement in congestion

MACA	RTS-CTS-DATA	53.07
MACAW	RTS-CTS-DS-DATA-ACK	49.07

Table 9: The throughput, in packets per second, achieved by a uncontested single stream.

- Wireless TCP

26

IEEE 802.11 Overview

- Adopted in 1997

Defines:

- MAC sublayer
- MAC management protocols and services
- Physical (PHY) layers
 - IR
 - FHSS
 - DSSS

27

802.11 particulars

- 802.11b (WiFi)
 - Frequency: 2.4 - 2.4835 Ghz DSSS
 - Modulation: DBPSK (1Mbps) / DQPSK (faster)
 - Orthogonal channels: 3
 - There are others, but they interfere. (!)
 - Rates: 1, 2, 5.5, 11 Mbps
- 802.11a: Faster, 5Ghz OFDM. Up to 54Mbps, 19+ channels
- 802.11g: Faster, 2.4Ghz, up to 54Mbps
- 802.11n: 2.4 or 5Ghz, multiple antennas (MIMO), up to 450Mbps (for 3x3 antenna configuration)

28

802.11 details

- Preamble
 - 72 bits @ 1Mbps, 48 bits @ 2Mbps
 - Note the relatively high per-packet overhead
- Control frames
 - RTS/CTS/ACK/etc.
- Management frames
 - Association request, beacons, authentication, etc.

29

Overview, 802.11 Architecture

30

802.11 modes

- Infrastructure mode
 - All packets go through a base station
 - Cards associate with a BSS (basic service set)
 - Multiple BSSs can be linked into an Extended Service Set (ESS)
 - Handoff to new BSS in ESS is pretty quick
 - Wandering around CMU
 - Moving to new ESS is slower, may require re-addressing
 - Wandering from CMU to Pitt
- Ad Hoc mode
 - Cards communicate directly.
 - Perform some, but not all, of the AP functions

31

802.11 Management Operations

- Scanning
- Association/Reassociation
- Time synchronization
- Power management

32

Scanning & Joining

- Goal: find networks in the area
- Passive scanning
 - No require transmission → saves power
 - Move to each channel, and listen for Beacon frames
- Active scanning
 - Requires transmission → saves time
 - Move to each channel, and send Probe Request frames to solicit Probe Responses from a network

33

Association in 802.11

34

Time Synchronization in 802.11

- Timing synchronization function (TSF)
 - AP controls timing in infrastructure networks
 - All stations maintain a local timer
 - TSF keeps timer from all stations in sync
- Periodic Beacons convey timing
 - Beacons are sent at well known intervals
 - Timestamp from Beacons used to calibrate local clocks
 - Local TSF timer mitigates loss of Beacons

35

Power Management in 802.11

- A station is in one of the three states
 - Transmitter on
 - Receiver on
 - Both transmitter and receiver off (dozing)
- AP buffers packets for dozing stations
- AP announces which stations have frames buffered in its Beacon frames
- Dozing stations wake up to listen to the beacons
- If there is data buffered for it, it sends a poll frame to get the buffered data

36

IEEE 802.11 Wireless MAC

- Support broadcast, multicast, and unicast
 - Uses ACK and retransmission to achieve reliability for unicast frames
 - No ACK/retransmission for broadcast or multicast frames
- Distributed and centralized MAC access
 - Distributed Coordination Function (DCF)
 - Point Coordination Function (PCF)

37

802.11 DCF (CSMA)

- Distributed Coordination Function (CSMA/CA)
- Sense medium. Wait for a DIFS (50 μ s)
- If busy, wait 'till not busy. Random backoff.
- If not busy, Tx.
- Backoff is binary exponential
- Acknowledgements use SIFS (short interframe spacing). 10 μ s.
 - Short spacing makes exchange atomic

802.11 DCF ([RTS/CTS]/Data/ACK)

39

Discussion

- RTS/CTS/Data/ACK vs. Data/ACK
 - Why/when is it useful?
 - What is the right choice
 - Why is RTS/CTS not used?

40

802.11 Rate Adaptation

- 802.11 spec specifies rates not algorithm for choices
 - 802.11b 4 rates, 802.11a 8 rates, 802.11g 12 rates
 - Each rate has different modulation and coding

Transmission Rate $\uparrow$ then Loss Ratio $\uparrow$
 Transmission Rate $\downarrow$ then Capacity Utilization $\downarrow$
 throughput decreases either way – need to get it just right

41

Auto Bit Rate (ABR) Algorithms

- Probe Packets
 - ARF
 - AARF
 - SampleRate
- Consecutive successes/losses
 - ARF
 - AARF
 - Hybrid Algorithm
- Physical Layer metrics
 - Hybrid Algorithm
 - RBAR
 - OAR
- Long-term statistics
 - ONOE
- SINR
 - Charm

Commercially Deployed:
ARF, SampleRate and ONOE

42

Carrier Sense

Desired result: concurrency

Desired result: time-multiplexing

Desired result: ???

43

Maybe Carrier Sense is Fine?

- "Far" interference:

– Small distance variation:
 $\Delta r_1 \approx \Delta r_2$

- "Near" interference:

– Nobody wants concurrency;
 $\text{SINR}_{\text{concurrent}} \ll \text{SNR}_{\text{multiplexing}}$

- In both cases, all receivers agree on preferring either multiplexing or concurrency
 - "Agreement" means CS can perform well
- Intermediate distance will be the hard case
- Also, shadows and obstacles?

44

Single Receiver, Sender and Interferer

$D = 55$

- Prefers concurrency
- Prefers multiplexing
- Starved w/o multiplexing

45

Interferer Position

Receiver preference vs. position:

$D = 20$

$D = 55$

$D = 120$

- Prefers concurrency
- Prefers multiplexing
- Starved w/o multiplexing

46

ABR Helps in Disagreements

- Intermediate distance can mean poor agreement! But...
- Does “mistaken” concurrency mean near-zero throughput? No. Adapts with lower bitrate.
- Does “mistaken” multiplexing mean 50%-reduced throughput? No. Adapts with higher bitrate.
- “Exposed” and “hidden” terminals are not very useful concepts with ABR

47

Carrier Sense + ABR Works Well

48

Key Assumptions

- ABR == Shannon
 - ABR is rarely this good
- Interference and ABR are both stable
 - Interference may be bursty/intermittent

49

Overview

- Wireless Background
- Wireless MAC
 - MACAW
 - 802.11
- **Wireless TCP**

50

Wireless Challenges

- Force us to rethink many assumptions
- Need to share airwaves rather than wire
 - Don't know what hosts are involved
 - Host may not be using same link technology
- Mobility
- Other characteristics of wireless
 - **Noisy** → lots of losses
 - **Slow**
 - Interaction of multiple transmitters at receiver
 - Collisions, capture, interference
 - Multipath interference

51

TCP Problems Over Noisy Links

- Wireless links are inherently error-prone
 - Fades, interference, attenuation
 - Errors often happen in bursts
- TCP cannot distinguish between corruption and congestion
 - TCP unnecessarily reduces window, resulting in low throughput and high latency
- Burst losses often result in timeouts
- Sender retransmission is the only option
 - Inefficient use of bandwidth

52

Constraints & Requirements

- Incremental deployment
 - Solution should not require modifications to fixed hosts
 - If possible, avoid modifying mobile hosts
- Probably more data to mobile than from mobile
 - Attempt to solve this first

53

Challenge #1: Wireless Bit-Errors

54

Performance Degradation

55

Proposed Solutions

- End-to-end protocols
 - Selective ACKs, Explicit loss notification
- Split-connection protocols
 - Separate connections for wired path and wireless hop
- Reliable link-layer protocols
 - Error-correcting codes
 - Local retransmission

56

Approach Styles (End-to-End)

- Improve TCP implementations
 - Not incrementally deployable
 - Improve loss recovery (SACK, NewReno)
 - Help it identify congestion (ELN, ECN)
 - ACKs include flag indicating wireless loss
 - Trick TCP into doing right thing → E.g. send extra dupacks
 - What is SMART?
 - DUPACK includes sequence of data packet that triggered it

57

Approach Styles (Split Connection)

- Split connections
 - Wireless connection need not be TCP
 - Hard state at base station
 - Complicates mobility
 - Vulnerable to failures
 - Violates end-to-end semantics

58

Split-Connection Congestion Window

- Wired connection does not shrink congestion window
- But wireless connection times out often, causing sender to stall

59

Approach Styles (Link Layer)

- More aggressive local retransmit than TCP
 - Bandwidth not wasted on wired links
- Adverse interactions with transport layer
 - Timer interactions
 - Interactions with fast retransmissions
 - Large end-to-end round-trip time variation
- FEC does not work well with burst losses

60

Hybrid Approach: Snoop Protocol

- Shield TCP sender from wireless vagaries
 - Eliminate adverse interactions between protocol layers
 - Congestion control only when congestion occurs
- The End-to-End Argument [SRC84]
 - Preserve TCP/IP service model: end-to-end semantics
 - *Is connection splitting fundamentally important?*
- Eliminate non-TCP protocol messages
 - *Is link-layer messaging fundamentally important?*

Fixed to mobile: transport-aware link protocol
Mobile to fixed: link-aware transport protocol

61

Snoop Overview

- Modify base station
 - to cache un-acked TCP packets
 - ... and perform local retransmissions
- Key ideas
 - No transport level code in base station
 - When node moves to different base station, state eventually recreated there

62

Snoop Protocol: CH to MH

- Snoop agent: *active interposition agent*
 - Snoops on TCP segments and ACKs
 - Detects losses by duplicate ACKs and timers
 - Suppresses duplicate ACKs from MH

63

Snoop Protocol: CH to MH

- Transfer of file from CH to MH
- Current window = 6 packets

64

Snoop Protocol: CH to MH

- Transfer begins

65

Snoop Protocol: CH to MH

- Snoop agent caches segments that pass by

66

Snoop Protocol: CH to MH

- Packet 1 is Lost

67

Snoop Protocol: CH to MH

- Packet 1 is Lost
 - Duplicate ACKs generated

68

Snoop Protocol: CH to MH

- Packet 1 is Lost
 - Duplicate ACKs generated
- Packet 1 retransmitted from cache at higher priority

69

Snoop Protocol: CH to MH

- Duplicate ACKs suppressed

70

Snoop Protocol: CH to MH

- Clean cache on new ACK

71

Snoop Protocol: CH to MH

- Clean cache on new ACK

72
