Who is Who

- **International Telecommunications Union (ITU)** - agency of the United Nations responsible for:
  - Assisting in the development and coordination of world-wide standards
  - Coordinate shared use of the global spectrum
  - Defined the International Mobile Telecommunications 2000 (IMT-2000) project for 3G telecommunications

- **Third Generation Partnership Project (3GPP)**
  - A group of telecommunications associations that represent large markets world-wide
  - Defined a group of 3G standards as part of the IMT-2000 framework in 1999
  - Originally defined GSM, EDGE, and GPRS
  - Later defined follow-on releases and also LTE (4G)

UMTS and WCDMA

- Part of a group of 3G standards defined as part of the IMT-2000 framework by 3GPP
- **Universal Mobile Telecommunications System (UMTS)**
  - Successor of GSM
- **W-CDMA** is the air interface for UMTS
  - Wide-band CDMA
  - Originally 144 kbps to 2 Mbps, depending on mobility
- Basically same architecture as GSM
  - Many GSM functions were carried over WCDMA
  - But they changed all the names!
Reminder: CDMA - Direct Sequence Spread Spectrum

Later Releases Improved Performance

• High Speed Downlink Packet Access (HSDPA): 1.8 to 14.4 Mbps downlink
  » Adaptive modulation and coding, hybrid ARQ, and fast scheduling
• High Speed Uplink Packet Access (HSUPA): Uplink rates up to 5.76 Mbps
• High Speed Packet Access Plus (HSPA+): Maximum data rates increased from 21 Mbps up to 336 Mbps
  » 64 QAM, 2×2 and 4×4 MIMO, and dual or multi-carrier combinations
• Eventually led to the definition of LTE

Advantages of CDMA for Cellular systems

• Frequency diversity – frequency-dependent transmission impairments have less effect on signal
• Multipath resistance – chipping codes used for CDMA exhibit low cross correlation and low autocorrelation
• Privacy – privacy is inherent since spread spectrum is obtained by use of noise-like signals
• Graceful degradation – system only gradually degrades as more users access the system

Mobile Wireless CDMA Soft Hand-off

• Soft Handoff – mobile station temporarily connected to more than one base station simultaneously
• Requires that the mobile acquire a new cell before it relinquishes the old
• More complex than hard handoff used in FDMA and TDMA schemes
Evolution of Cellular Wireless Systems

Overview LTE

- Motivation
- Architecture
- Resource management
- LTE protocols
- Radio access network
  » OFDM refresher
- LTE advanced

Purpose, motivation, and approach to 4G

- Defined by ITU directives for International Mobile Telecommunications Advanced (IMT-Advanced)
- All-IP packet switched network.
- Ultra-mobile broadband access
- Peak data rates
  » Up to 100 Mbps for high-mobility mobile access
  » Up to 1 Gbps for low-mobility access
- Dynamically share and use network resources
- Smooth handovers across heterogeneous networks
  » 2G and 3G networks, small cells such as picocells, femtocells, and relays, and WLANs
- High quality of service for multimedia applications

High Level Features

- No support for circuit-switched voice
  » Instead providing Voice over LTE (VoLTE)
- Replace spread spectrum/CDMA with OFDM

LTE Architecture

- evolved NodeB (eNodeB)
  - Most devices connect into the network through the eNodeB
- Evolution of the previous 3GPP NodeB (~2G BTS)
  - Uses OFDM instead of CDMA
- Has its own control functionality
  - Dropped the Radio Network Controller (RNC - ~2G BSC)
  - eNodeB supports radio resource control, admission control, and mobility management (handover)
  - Was originally the responsibility of the RNC

Evolved Packet System

- Overall architecture is called the Evolved Packet System (EPS)
- 3GPP standards divide the network into
  - Radio access network (RAN): cell towers and connectives to mobile devices
  - Core network (CN): management and connectivity to other networks
- Each can evolve independently
  - Driven by different technologies: optimizing spectrum use versus management and control or traffic

Evolved Packet System Components

- Long Term Evolution (LTE) is the RAN
  - Called Evolved UMTS Terrestrial Radio Access (E-UTRA)
  - Enhancement of 3GPP’s 3G RAN
  - eNodeB is the only logical node in the E-UTRAN
  - No Radio Network Controller (RNC)
- Evolved Packet Core (EPC)
  - Operator or carrier core network – core of the system
  - Traditionally circuit switched but now entirely packet switched
    - Based on IP - Voice supported using voice over IP (VoIP)

Design Principles of the EPS

- Packet-switched transport for traffic belonging to all QoS classes
  - Voice, streaming, real-time, non-real-time, background
- Comprehensive radio resource management
  - End-to-end QoS, transport for higher layers
  - Load sharing/balancing
  - Policy management across different radio access technologies
- Integration with existing 3GPP 2G and 3G networks
- Scalable bandwidth from 1.4 MHz to 20 MHz
- Carrier aggregation for overall bandwidths up to 100 MHz
Evolved Packet Core Components

- Mobility Management Entity (MME)
  - Supports user equipment context, identity, authentication, and authorization
- Serving Gateway (SGW)
  - Receives and sends packets between the eNodeB and the core network
- Packet Data Network Gateway (PGW)
  - Connects the EPC with external networks
- Home Subscriber Server (HSS)
  - Database of user-related and subscriber-related information
- Interfaces
  - S1 interface between the E-UTRAN and the EPC
    - For both control purposes and for user plane data traffic
  - X2 interface for eNodeBs to interact with each other
    - Again for both control purposes and for user plane data traffic

“Wireless Communication Networks and Systems”

LTE Resource Management

- LTE uses bearers for quality of service (QoS) control instead of circuits
- EPS bearers
  - Between entire path between PGW and UE
  - Maps to specific QoS parameters such as data rate, delay, and packet error rate
- Service Data Flows (SDFs) differentiate traffic flowing between applications on a client and a service
  - SDFs must be mapped to EPS bearers for QoS treatment
  - SDFs allow traffic types to be given different treatment
- End-to-end service is not completely controlled by LTE

Bearer Management based on QoS Class Identifier (QCI)

* QCI value typically used for the default bearer

Guaranteed (minimum) Bit Rate

No Guarantees
EPC: Mobility Management

- X2 interface used when moving within a RAN coordinated under the same Memory Management Entity (MME)
- S1 interface used to move to another MME
- **Hard handovers** are used: A UE is connected to only one eNodeB at a time

EPC: Inter-cell Interference Coordination (ICIC)

- Reduces interference when the same frequency is used in a neighboring cell
- Goal is universal frequency reuse
  - \( N = 1 \) in “Cellular principles” lecture
  - Must avoid interference when mobile devices are near each other at cell edges
  - Interference randomization, cancellation, coordination, and avoidance are used
- eNodeBs send **indicators**
  - Relative Narrowband Transmit Power, High Interference, and Overload indicators
- Later releases of LTE have improved interference control
  - “Cloud RAN”: use a cloud to manage interference, spectrum

Protocol Layers End-to-End

Some slides based on material from
Protocol Layers

PDCP and RLC

- **Packet Data Convergence Protocol (PDCP)**
  - Delivers packets from UE to eNodeB
  - Involves header compression, ciphering, integrity protection, in-sequence delivery, buffering and forwarding of packets during handover

- **Radio Link Control (RLC)**
  - Segments or concatenates data units
  - Performs ARQ when MAC layer H-ARQ fails
    - ARQ: Automatic Repeat Request (retransmission)
    - H-ARQ: Hybrid ARQ – combines FEC and ARQ

Protocol Layers

MAC and PHY

- **Medium Access Control (MAC)**
  - Performs H-ARQ: combines FEC and retransmission (ARQ)
  - Prioritizes and decides which UEs and radio bearers will send or receive data on which shared physical resources
  - Decides the transmission format, i.e., the modulation format, code rate, MIMO rank, and power level

- **Physical layer actually transmits the data**

Overview

- **Radio access network**
  - OFDM refresher
- **LTE advanced**

Some slides based on material from
“Wireless Communication Networks and Systems”
Different Solution for Up and Downlink

- The downlink uses OFDM with Multiple Access (OFDMA)
  - Multiplexes multiple mobiles on the same subcarrier
  - Improved flexibility in bandwidth management, e.g., multiple low bandwidth users can share subcarriers
  - Enables per-user frequency hopping to mitigate effects of narrowband fading

- The uplink uses Single Carrier OFDM (SC-OFDM)
  - OFDM but using a single carrier
  - Provides better energy and cost efficiency for battery-operated mobiles
  - Large number of subcarriers leads to high peak-to-average Power ratio (PAPR), which is energy-inefficient

LTE Radio Access Network

- LTE uses both TDD and FDD
  - Both have been widely deployed

- Time Division Duplexing (TDD)
  - Uplink and downlink transmit in the same frequency band, but alternating in the time domain

- Frequency Division Duplexing (FDD)
  - Different frequency bands for uplink and downlink

- LTE uses two cyclic prefixes (CPs)
  - Extended CP is for worse environments

Spectrum Allocation for FDD and TDD

- LTE uses both TDD and FDD
  - Both have been widely deployed

- Time Division Duplexing (TDD)
  - Uplink and downlink transmit in the same frequency band, but alternating in the time domain

- Frequency Division Duplexing (FDD)
  - Different frequency bands for uplink and downlink

- LTE uses two cyclic prefixes (CPs)
  - Extended CP is for worse environments
Resource Blocks

- A time-frequency grid is used to illustrate allocation of physical resources
- Each column is 6 or 7 OFDM symbols per slot
- Each row corresponds to a subcarrier of 15 kHz
  - Some subcarriers are used for guard bands
  - 10% of bandwidth is used for guard bands for channel bandwiths of 3 MHz and above

FDD Frame Structure
