The email (edited)

Mars Exploration Rover

Subject: I need your advice/help
From: Robert.Manning @ jpl
Date: 11/1/01 1:14 PM
To: Stewart.Collins @ jpl, Andrew.Johnson @ jpl

I'm Rob Manning. I'm the systems engineering manager and EDL Phase manager for MER.

MER has a problem that I think might be solvable with a little help from you.

It re-occurred to me that a measure of our absolute (ground relative) velocity would go a long way to mitigating the steady-state contribution of winds....

... two images taken during terminal descent might "easily" provide the data necessary.

Andy J. would you care to comment here?

DIMES Camera

DIMES Hardware

Mars Exploration Rover

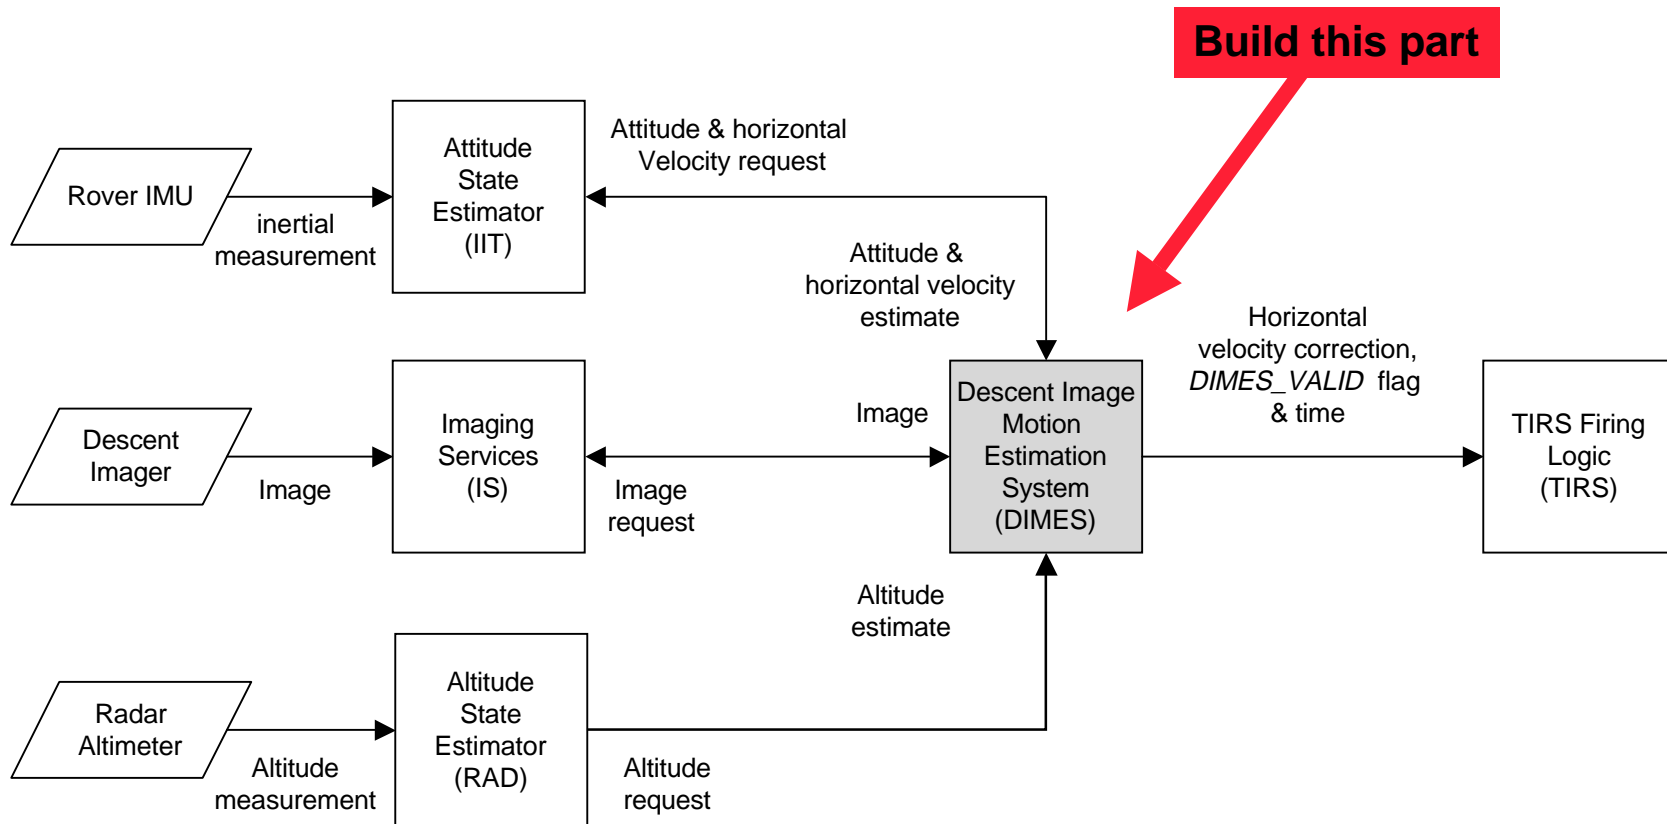

DIMES Functional Block Diagram

Mars Exploration Rover

Challenges to Development of DIMES

Mars Exploration Rover

- Development from concept to flight qualified system in **26 months** before landing
 - accommodate camera and software into mature EDL system with minimal impact
- Numerous non-ideal imaging effects possible during EDL
 - bland landing sites, dust, cosmic rays, heatshield
- Algorithm must **never** generate an **incorrect** velocity
 - algorithm must be self checking
- Algorithm must run with minimal processing resources
 - 20% of 20 MHz RAD6000 for 20 seconds
- MER cameras not designed for descent imaging
 - motion blur, frame transfer smear, long readout time
- Imaging in the loop never used during EDL
 - **skeptics** wanted to kill the development
- Development must be low cost

DIMES Motion Estimation Concept

(not the actual optimized order of operations)

Mars Exploration Rover

Correct Images

- Bin each image
- Radiometric correction of each image.
- Rectify each image to ground plane using IMU attitude and radar altitude.

Correlate Images

- Apply Interest Operator to first image.
- Select high contrast template in image overlap that avoids zero phase spot.
- Slide template over window in second image and at each pixel compute linear correlation coefficient between template and window DN.
- Find maximum correlation and compute correlation performance metrics.
- Compute horizontal velocity from template shift and VALID measurement.

DIMES Algorithm

Mars Exploration Rover

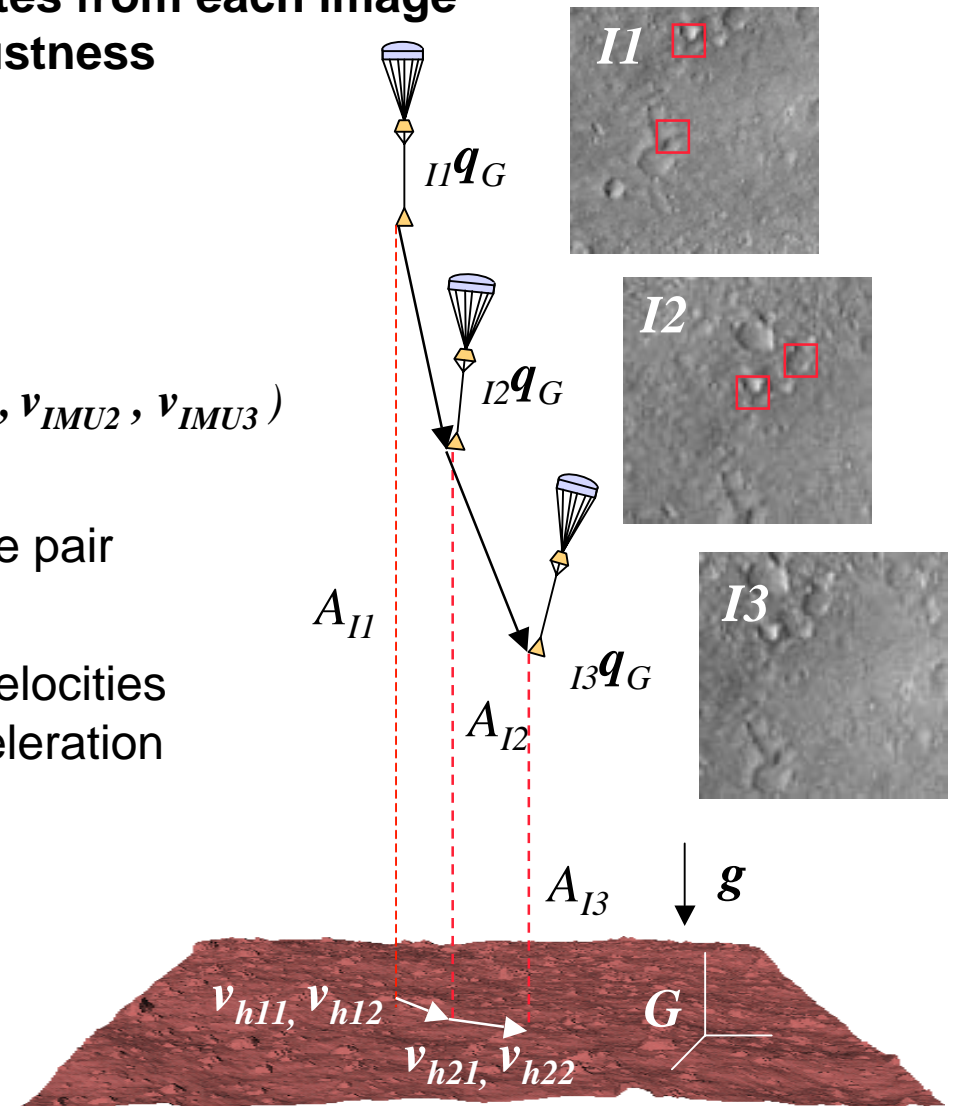

Using three images and two templates from each image pair improves overall DIMES robustness

- Input

- 3 images (I_1, I_2, I_3)
- 3 IMU attitudes (${}_{II}q_G, {}_{I2}q_G, {}_{I3}q_G$)
- 3 radar altitudes (A_{I1}, A_{I2}, A_{I3})
- 3 IMU horizontal velocities ($v_{IMU1}, v_{IMU2}, v_{IMU3}$)

- Algorithm

- track two templates in each image pair
- verify correlation of templates
- compare difference of template velocities between image pairs to IMU acceleration

DIMES Algorithm Details

Image Binning

Mars Exploration Rover

1024x1024

Hardware
Binning

256x1024

- **Purpose: Reduce Computation**
- **Descent Camera bins image rows in hardware**
 - 1024x1024 to 256x1024
 - Adds charge
- **DIMES algorithm bins image columns**
 - 256x1024 to 256x256
 - Add DN instead of averaging

Software
Binning

256x256

Radiometric Correction

Mars Exploration Rover

- Purpose: Reduce Differences Between Images
- Remove known radiometric distortions
 - Dark current (subtract a constant look up table)
 - Frame transfer ramp (subtract ramp that is computed based on signal)
 - CCD pixel to pixel variations (multiply by scale factor lookup table)
 - Optical transfer/radiometric fall off (multiply by scale factor lookup table)
- Cannot remove unknown photometric differences
- Memory Efficient Implementation
 - Offset and scale images are computed by fitting a line to multiple images taken inside an integrating sphere at different exposure times
 - Bi-quartic polynomials are fit to scale and offset images (15 coefficients) and stored
 - During EDL, but before image acquisition, scale and offset images are pre-computed from the bi-quartic polynomials

Image Rectification Concept

Mars Exploration Rover

Descent Image

Rectification

Rectified Image

Rectification transforms a descent image into an image that would be seen by a virtual camera looking straight down.

Image Rectification

Mars Exploration Rover

- **Rectification removes orientation and scale differences between images**
 - Both images rectified to a virtual camera at altitude of first image
- **Requires position and attitude of camera in ground frame**
 - Ground relative attitude comes from IMU
 - Use altitude from radar altimeter for vertical position
 - Assume lander is dropping straight down (i.e., horizontal position is zero)
- **Based on flat surface approximation**
 - Surface slope and terrain relief introduce minor errors in rectification
 - high altitude
 - landing site safety requires small slopes and terrain relief

Image Rectification With Radial Distortion

Mars Exploration Rover

- **Objective**
 - To remove radial distortion and rectify image data to the ground plane.
- **Approach**
 - The templates and windows are small.
 - Radial distortion is approximately linearly in a small area.
 - Use a homography transformation (linear) to rectify templates and windows

$$X = \frac{a_1x + a_2y + a_3}{a_7x + a_8y + 1} \quad Y = \frac{a_4x + a_5y + a_6}{a_7x + a_8y + 1}$$

- **Algorithm**
 - The rectified positions of the four corners of the template are determined directly using the camera model that includes radial distortion.
 - These four points are used to estimate the parameters of the homography transform.
 - The template is rectified using this transform.
- **Approach is much faster than using camera model directly**
 - Avoids the slow and iterative between image 2d and 3d computations.
 - Current pixel rectification can use the result from the previous pixel.
 - Suitable to any camera model.

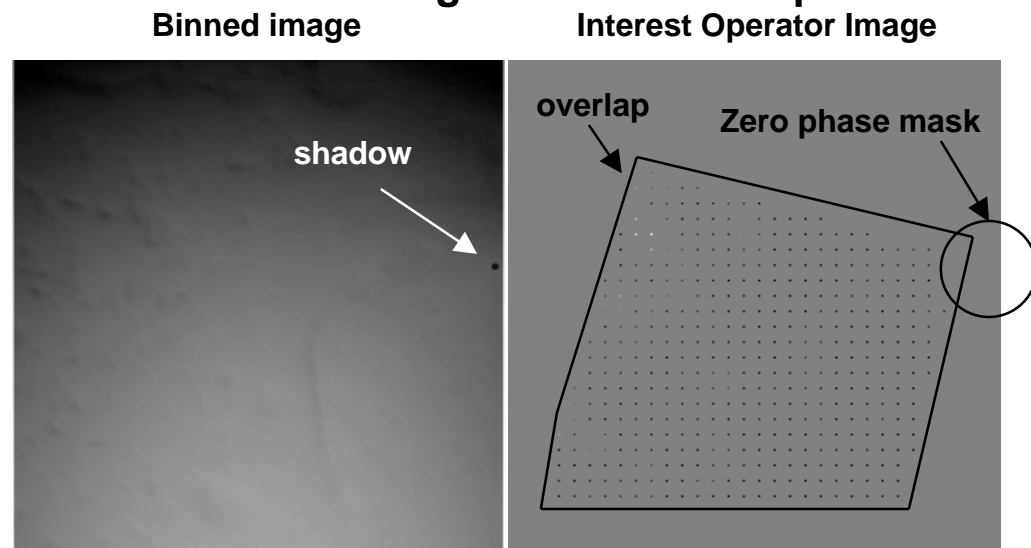

Template Selection

Mars Exploration Rover

- **Standard Interest operator**
 - smallest eigenvalue of template autocorrelation
- **Efficient Implementation**
 - Interest operator computed before rectification and image flattening
 - Only template and window need to be rectified and flattened
 - Computed on a coarse grid
 - Width of template broadens interest operator peaks, so skip pixels
- **Application Region**
 - Only computed in overlap region of images
 - Sun direction parameter is used to mask out region around zero phase
 - Zero phase brightening
 - Parachute shadow

Two Stage Correlation

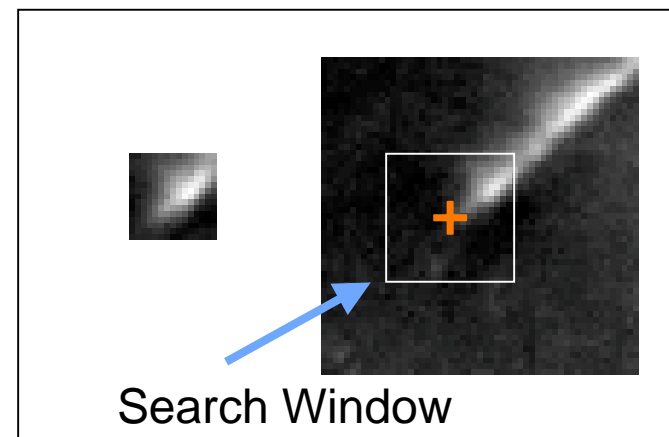

Mars Exploration Rover

- **Pseudo-normalized correlation**

$$R = (2 \sum_T \tilde{I}_1 * \tilde{I}_2) / (\sum_T \tilde{I}_1^2 + \sum_T \tilde{I}_2^2)$$
$$\tilde{I}_i = I_i - \sum_T I_i / N$$

- **Speed up correlation by applying it at a coarse and then fine image resolution.**
 1. **Generate coarse data by binning template and search window to 2x2 resolution**
 2. **Correlate coarse template and window to get best and second best match locations**
 3. **Project the best correlation locations into the 1x1 resolution window.**
 4. **Find the best correlations in a smaller window around the projected point.**
- **Results in 2x speed improvement over single stage correlation**

Correlation Performance Metrics

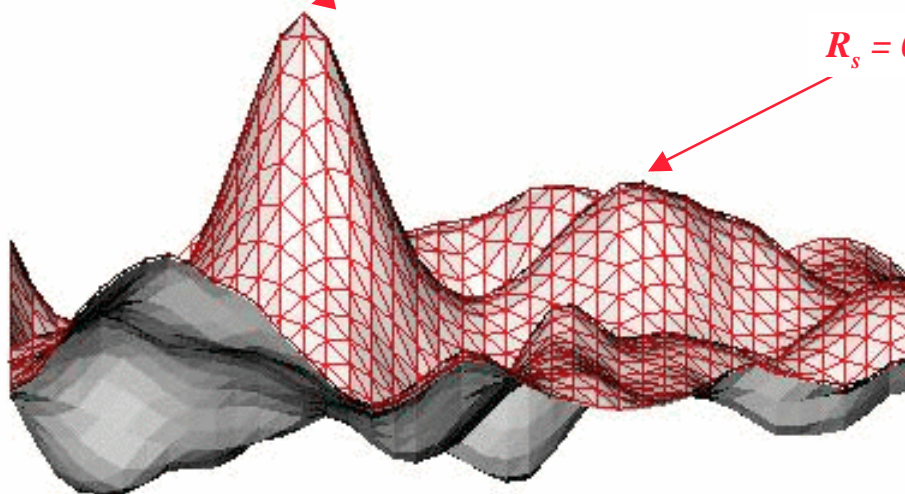

Mars Exploration Rover

Correlation performance metrics are used to detect false correlations that can lead to incorrect velocity estimates

Peak Ratio
 $P = R/R_s = 2.5$

Correlation
 $R = 0.97$

$R_s = 0.39$

$V_{err} = (0.6, 0.8) \text{ m/s}$

IMU Check on Image Velocities

Mars Exploration Rover

If equal then IMU confirms image velocities

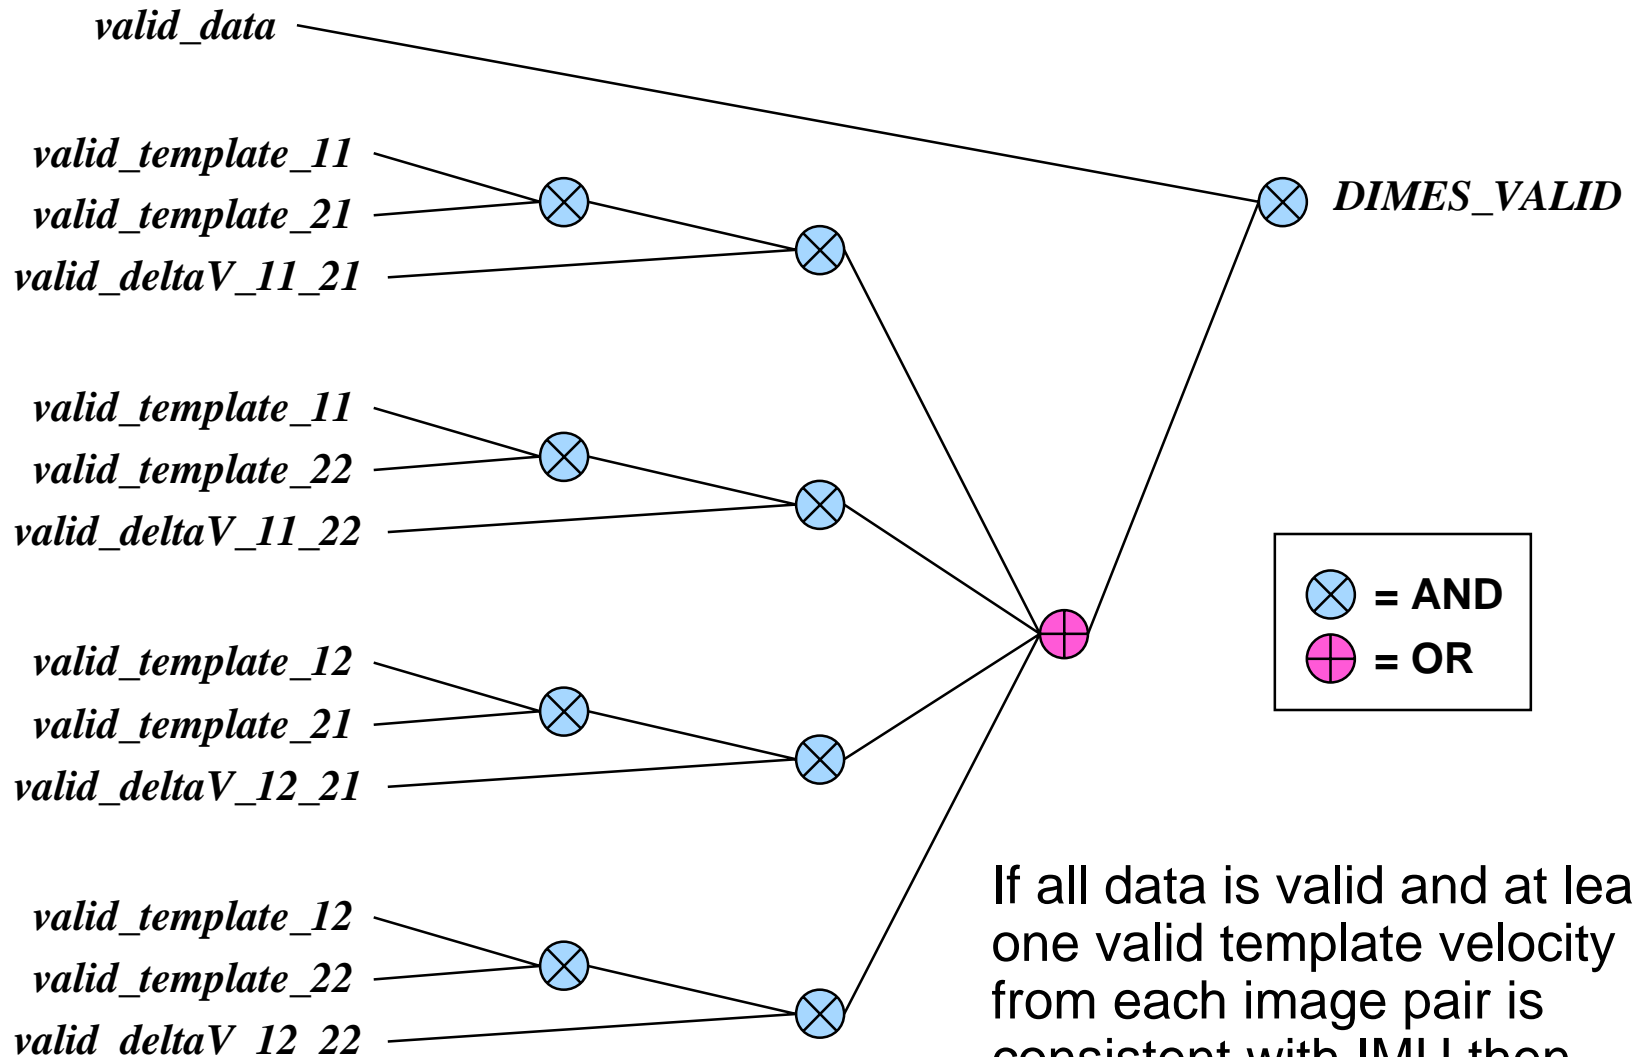

DIMES Logic Diagram

Mars Exploration Rover

If all data is valid and at least one valid template velocity from each image pair is consistent with IMU then DIMES reports a velocity.

Testing and Verification

Monte Carlo Simulation with Simulated Imagery
Field Testing with Engineering Model Sensors

MOC2DIMES

Simulating Descent Imagery with MOC Imagery

- Process MOC to I/F (USGS)
- Extract position and attitude of camera from EDL simulation trajectories
- Add photometric effects
 - Zero-phase brightening
 - Parachute shadow
- Render descent image light field
 - Motion blur
- Pass light field through high fidelity model of camera electronics
 - Frame transfer
 - Noise sources

DIMES Verification

Mars Exploration Rover

- **The 3 images on the following pages are the DIMES images rectified to the local level frame. The position and attitude for rectification come from onboard measurements: attitude from IIT, altitude from RAS, horizontal motion from DIMES. For the images, North is left and East is down.**
- **As you flip through the pages, you will see that in the overlap there is very little shift in image data. Qualitatively, this indicates that all of the measurements are consistent and specifically that the horizontal velocity computed by DIMES was correct.**

Spirit DIMES/TIRS Vector Diagram

Mars Exploration Rover

(4.1, 9.7) m/s

steady state computed by DIMES

(-6.8, 22.4) m/s

propagated sum of DIMES and RAD-induced at bridle cut that would have occurred had TIRS not fired

(-11.0, 0) m/s

total at airbag release after RAD and TIRS

On Spirit, had DIMES not been used, the impact velocity would have been at the limit of the airbag capability and Spirit may have bounced into Endurance Crater. By using DIMES, the velocity was reduced to well within the bounds of the airbag performance and Spirit arrived safely at Mars.

View of Entry Trajectory

Mars Exploration Rover

The next 6 slides show different views of the EDL trajectory superimposed on a mosaic of the DIMES images.

This visualization is one of several pieces of information used to determine the location of Opportunity on the surface.

The EDL trajectory is a straight integration of acceleration using the DIMES velocity as an initial condition.

The DIMES images are mosaiced using IIT attitude, RAS altitude and DIMES horizontal motion estimates.

Current and Future Work

JPL Autonomous Helicopter Testbed

Mars Exploration Rover

Commercial Model Helicopter

- 9 kg payload capacity
- 1.8 meter main rotor diameter
- Twin cylinder engine, runs on gas/oil mixture
- 15-20 minute flight on single tank of fuel (can extend flight time with additional/larger tanks)

Sensors

- CCD imager (640x480 grayscale)
- Laser altimeter
- IMU
- DGPS (2 cm CEP accuracy)
- Compass/Inclinometer

Onboard Computing

- PC/104+ architecture
- 700 MHz PIII CPU with 128Mb DRAM and 128 Mb flash disk
- Framegrabber
- Timer/counter and DIO
- Quad serial card

Communication and Control

- 11 Mbit/s wireless ethernet link
- Laptop for robot control and telemetry display

Dense Structure From Motion Landing Hazard Avoidance Algorithm

Mars Exploration Rover

1. Select and track features between two images
2. Estimate motion and coarse topography
3. Track dense feature grid using motion and coarse topography to reduce search
4. Construct terrain map
5. Apply slope and roughness hazard detection and avoidance
