Homework 5: Parallelism and Control Flow
15-814: Types and Programming Languages
Fall 2015
TA: Evan Cavallo (ecavallo@cs.cmu.edu)

SOLUTIONS

Out: 11/5/15
Due: 11/17/15, 10:30am

1 Cost Dynamics

In this section, we will relate cost dynamics to sequential and parallel dynamics. Consider a language containing products.

\[ \tau ::= \cdots \mid \tau \times \tau \]

\[ e ::= \cdots \mid \langle e, e \rangle \mid e \cdot L \mid e \cdot R \]

In class, we defined a judgment \( e \Downarrow c v \), which states that \( e \) evaluates to \( v \) with cost graph \( c \). We defined a grammar of cost graphs like so:

\[ c ::= 0 \mid 1 \mid c \oplus c \mid c \otimes c \]

Here, \( 0 \) denotes a computation with zero cost and \( 1 \) represents a single unit of computation. The graph \( c_1 \oplus c_2 \) is the sequential composition of the graphs \( c_1 \) and \( c_2 \), while \( c_1 \otimes c_2 \) is the parallel composition. To each cost graph \( c \) we associate two numbers, the work

\[ wk(0) = 0 \]

\[ wk(1) = 1 \]

\[ wk(c_1 \oplus c_2) = wk(c_1) + wk(c_2) \]

\[ wk(c_1 \otimes c_2) = wk(c_1) + wk(c_2) \]

and the depth

\[ dp(0) = 0 \]

\[ dp(1) = 1 \]

\[ dp(c_1 \oplus c_2) = dp(c_1) + dp(c_2) \]

\[ dp(c_1 \otimes c_2) = \max\{dp(c_1), dp(c_2)\} \]

The two differ only in the case of \( c_1 \otimes c_2 \) – while the work of a parallel composition is the sum of the work of the components, the depth is the longer of the component depths.

We also defined sequential and parallel versions of the structural operational dynamics, given by judgments \( e \mapsto m e' \) and \( e \mapsto par e' \). These differ on the rules for evaluating pairs: while \( \mapsto seq \) evaluates the first component of a pair before the second, \( \mapsto par \) evaluates the two simultaneously.

\[ \frac{e_1 \mapsto seq e_1'}{\langle e_1, e_2 \rangle \mapsto seq \langle e_1', e_2 \rangle} (PAIR-S1) \]

\[ \frac{e_1 \text{ val } e_2 \mapsto seq e_2'}{\langle e_1, e_2 \rangle \mapsto seq \langle e_1, e_2' \rangle} (PAIR-S2) \]

\[ \frac{e_1 \mapsto par e_1'}{\langle e_1, e_2 \rangle \mapsto par \langle e_1', e_2 \rangle} (PAIR-P1) \]

\[ \frac{e_1 \text{ val } e_2 \mapsto par e_2'}{\langle e_1, e_2 \rangle \mapsto par \langle e_1, e_2' \rangle} (PAIR-P2) \]

\[ \frac{e_1 \mapsto par e_1' \quad e_2 \text{ val}}{\langle e_1, e_2 \rangle \mapsto par \langle e_1', e_2 \rangle} (PAIR-P3) \]

The rules for evaluating projections are the same for both evaluation strategies (let \( m \in \{seq, par\} \)):

\[ \frac{e \mapsto m e'}{e \cdot L \mapsto m e' \cdot L} (PROJL-1) \]

\[ \frac{e_1 \text{ val } e_2 \text{ val}}{\langle e_1, e_2 \cdot L \rangle \mapsto m e_1} (PROJL-2) \]

(The rules for \( e \cdot R \) are completely symmetric.) We want our definition \( e \Downarrow c v \) to cohere with the two operational dynamics definitions, in the sense of the following proposition.
Proposition 1 *Correction 11/16/15: Fixed statement.* For an expression $e$ and value $v$, $e \leftrightarrow e_{\text{seq}}^m v$ if and only if there exists $c$ with $e \downarrow^c v$ and $\text{wk}(c) = w$. Likewise, $e \leftrightarrow e_{\text{par}}^d v$ if and only if there exists $c$ with $e \downarrow^c v$ and $\text{dp}(c) = d$.

Here, the judgment $e \leftrightarrow e_{\text{seq}}^m e'$ expresses that $e$ steps to $e'$ in $n$ steps, and is defined by the following rules:

$$
\frac{e \leftrightarrow e_{\text{seq}}^m e'}{e \leftrightarrow e_{\text{seq}}^0 e} \quad \frac{e \leftrightarrow e_{\text{seq}}^{m+1} e'}{e \leftrightarrow e_{\text{seq}}^m e''}
$$

**Task 1** Define rules for $e \downarrow^c v$ covering the cost graph dynamics of products (pairing and projections). You may want to do this task in tandem with Task 4, which could help you determine what the cost graph annotations should be. Your definition should also satisfy Lemma 2 below.

For a refresher on evaluation dynamics, see PFPL 7.

**Solution:**

$$
\begin{align*}
&e_1 \downarrow^c v_1 \quad e_2 \downarrow^c v_2 \\
&\langle e_1, e_2 \rangle \downarrow^c_{\text{seq}} (v_1, v_2) \quad (V-1) \\
&e \downarrow^c \langle v_1, v_2 \rangle \\
&\frac{e \leftrightarrow_{\text{seq}} e'}{e \leftrightarrow_{\text{par}} e'} \quad (V-2) \\
&e \downarrow^c \langle v_1, v_2 \rangle
\end{align*}
$$

To show the forward direction(s) of Proposition 1, we use a head expansion lemma. Combined with Lemma 2 below, which you may use without proof, the theorem quickly follows.

**Lemma 1** If $e \downarrow^c v$ and $e \downarrow \text{val}$, then $\text{wk}(c) = \text{dp}(c) = 0$. Conversely, if $e \downarrow \text{val}$ then there exists $c$ with $\text{wk}(c) = \text{dp}(c) = 0$ and $e \downarrow^c v$.

**Task 2 (Head Expansion)** Using the definitions you gave in Task 4, show the following:

(a) If $e' \downarrow^c v'$ and $e \leftrightarrow_{\text{seq}} e'$, then there exists $c$ with $e \downarrow^c v$ and $\text{wk}(c) = \text{wk}(c') + 1$.

(b) If $e' \downarrow^c v'$ and $e \leftrightarrow_{\text{par}} e'$, then there exists $c$ with $e \downarrow^c v$ and $\text{dp}(c) = \text{dp}(c') + 1$.

Go by induction on the derivation of $m \rightarrow e'$. For (a), give the case for (PAIR-S1). For (b), give the cases for (PAIR-P1), (PAIR-P2), (PROJL-1), and (PROJL-2).

**Solution:**

(a) Case (PAIR-S1): Here our assumptions are $\langle e_1', e_2' \rangle \downarrow^c v$ and $\langle e_1, e_2 \rangle \rightarrow_{\text{seq}} \langle e_1', e_2' \rangle$ derived from $e_1 \rightarrow_{\text{seq}} e_1'$. By inversion on the derivation of $\langle e_1', e_2' \rangle \downarrow^c v$, we know $c = c_1 \otimes c_2$ and $v = \langle v_1, v_2 \rangle$ with $e_1' \downarrow^c v_1$ and $e_2' \downarrow^c v_2$. By induction hypothesis applied to $e_1' \downarrow^c v_1$ and $e_1 \rightarrow_{\text{seq}} e_1'$, there exists $c_1'$ such that $\text{wk}(c_1') = \text{wk}(c_1) + 1$ and $e_1 \downarrow^c v_1$. It follows by (V-1) that $\langle e_1, e_2 \rangle \downarrow^c \langle c_1 \otimes c_2, v_1, v_2 \rangle$, and $\text{wk}(c_1' \otimes c_2) = \text{wk}(c_1) + 1 + \text{wk}(c_2) = \text{wk}(c) + 1$ as needed.

(b) Case (PAIR-P1): Here we assume $\langle e_1', e_2' \rangle \downarrow^c v$ and $\langle e_1, e_2 \rangle \rightarrow_{\text{par}} \langle e_1', e_2' \rangle$ derived from $e_1 \rightarrow_{\text{par}} e_1'$ and $e_2 \rightarrow_{\text{par}} e_2'$. By inversion on the derivation of $\langle e_1', e_2' \rangle \downarrow^c v$, we know $c = c_1 \otimes c_2$ and $v = \langle v_1, v_2 \rangle$ with $e_1' \downarrow^c v_1$ and $e_2' \downarrow^c v_2$. By induction hypothesis applied to $e_1' \downarrow^c v_1$ and $e_1 \rightarrow_{\text{par}} e_1'$, there exists $c_1'$ such that $\text{dp}(c_1') = \text{dp}(c_1) + 1$ and $e_1 \downarrow^c v_1$. Likewise, there is $c_2'$ such that $\text{dp}(c_2') = \text{dp}(c_2) + 1$ and $e_2 \downarrow^c v_2$. It follows by (V-1) that $\langle e_1, e_2 \rangle \downarrow^c \langle c_1 \otimes c_2, v_1, v_2 \rangle$, and $\text{dp}(c_1' \otimes c_2') = \text{dp}(c_1) + 1$ as needed.

Case (PAIR-P2): Here we assume $\langle e_1, e_2' \rangle \downarrow^c v$ and $\langle e_1, e_2 \rangle \rightarrow_{\text{par}} \langle e_1, e_2' \rangle$ derived from $\text{val}_{e_1}$ and $e_2 \rightarrow_{\text{par}} e_2'$. By inversion on the derivation of $\langle e_1, e_2' \rangle \downarrow^c v$, we know $c = c_1 \otimes c_2$ and $v = \langle v_1, v_2 \rangle$ with $e_1 \downarrow^c v_1$ and $e_2' \downarrow^c v_2$. Since $e_1 \text{ val}$, we have by Lemma 2 that $\text{dp}(c_1) = 0$. By induction hypothesis applied to $e_2' \downarrow^c v_2$ and $e_2 \rightarrow_{\text{par}} e_2'$, there exists $c_2'$ such that $\text{dp}(c_2') = \text{dp}(c_2) + 1$ and $e_2 \downarrow^c v_2$. It follows by (V-1) that
\[\langle e_1, e_2 \rangle \Downarrow \epsilon_1 \otimes \epsilon_2 \ (v_1, v_2).\] Since \(\text{dp}(e_1) = 0\), we know \(\text{dp}(\epsilon_1 \otimes \epsilon_2) = \max\{\text{dp}(e_1), \text{dp}(e_2)\} = \text{dp}(e_2) = \text{dp}(e_2) + 1 = \max\{\text{dp}(e_1), \text{dp}(e_2)\} + 1 = \text{dp}(e) + 1.\)

- Case (\text{ProjL-1}): Here we assume \(\epsilon' : \mathcal{L} \Downarrow v\) and \(e : \mathcal{L} \rightarrow_{\text{par}} \epsilon' \cdot \mathcal{L}\) derived from \(e \rightarrow_{\text{par}} e'\). By inversion on the derivation of \(\epsilon' : \mathcal{L} \Downarrow v\) we know \(\epsilon = \epsilon' \otimes v\) and \(\epsilon : \mathcal{L} \Downarrow_1 (v, v_2)\) for some \(v_2\). By induction hypothesis applied with \(\epsilon'\), there exists \(c'\) such that \(\epsilon : \mathcal{L} \Downarrow_1 (v, v_2)\) and \(\text{dp}(c') = \text{dp}(e') + 1\). By (V-2), then, \(\epsilon \cdot \mathcal{L} \Downarrow_{\epsilon' \otimes 1} v\), and we have \(\text{dp}(c' \oplus 1) = \text{dp}(c'' + 1) = \text{dp}(e') + 2 = \text{dp}(c' \oplus 1) + 1 = \text{dp}(e) + 1.\)

- Case (\text{ProjL-2}): Here we assume \(e_1 \Downarrow c\ v\) and \(\langle e_1, e_2 \rangle \cdot \mathcal{L} \rightarrow_{\text{par}} e_1\) derived from \(e_1\) \(\text{val}\) and \(e_2\) \(\text{val}\). By Lemma 1 we know there exists \(c'\) with \(e_2 \Downarrow c' e_2\) and \(\text{dp}(c') = 0\). Now we have:

\[
\frac{e_1 \Downarrow c\ v \quad e_2 \Downarrow c'\ e_2}{\langle e_1, e_2 \rangle \Downarrow c \otimes c' \langle v, e_2 \rangle} \quad (V-1)
\]

\[
\frac{e_1 \Downarrow c\ v \quad e_2 \Downarrow c'\ e_2}{\langle e_1, e_2 \rangle \cdot \mathcal{L} \Downarrow (c \otimes c') \oplus 1\ v} \quad (V-2)
\]

and \(\text{dp}(c \otimes c') + 1 = \text{dp}(c) + 1 = \max\{\text{dp}(c), \text{dp}(c')\} + 1 = \max\{\text{dp}(c), 0\} + 1 = \text{dp}(e) + 1.\)

## 2 Continuations

In this section, we will write some programs using continuations and show how to encode continuations in a language without them. We’ll start with a language with continuations which is evaluated using a control stack.

\[
\tau ::= \text{nat} \mid \tau \rightarrow \tau \mid \tau \times \tau \mid \tau + \tau \mid \tau \text{ cont}
\]

\[
e ::= \cdots \mid \text{cont}(k) \mid \text{letcc}(\tau)(x, e) \mid \text{throw}(\tau)(e; e)
\]

\[
k ::= \epsilon \mid k; f
\]

\[
f ::= \cdots \mid \text{throw}(\tau)(-; e) \mid \text{throw}(\tau)(e; -)
\]

We use an eager evaluation strategy for all of the constructs in the language. Evaluation of continuations is given by the following rules (see PFPL 30.2 for more details and statics rules).

\[
k \triangleright \text{cont}(k') \rightarrow k \oplus \text{cont}(k')
\]

\[
k \triangleright \text{letcc}(\tau)(x, e) \rightarrow k \triangleright [\text{cont}(k)/x]e
\]

\[
k \triangleright \text{throw}(\tau)(e_1; e_2) \rightarrow k; \text{throw}(\tau)(-; e_2) \triangleright e_1
\]

\[
k; \text{throw}(\tau)(-; e_2) \triangleleft e_1 \rightarrow k; \text{throw}(\tau)(e_1; -) \triangleright e_2
\]

\[
k; \text{throw}(\tau)(e_1; -) \triangleleft \text{cont}(k') \rightarrow k' \triangleleft e_1
\]

### 2.1 Programming with Continuations

To start off, we’ll write a few basic programs with continuations. An example, which we covered in class and which may be useful in Task 3, is the function \(\text{ccwf} : (\tau_1 \rightarrow \tau_2) \rightarrow (\tau_2 \text{ cont} \rightarrow \tau_1 \text{ cont})\), “compose continuation with function.”

\[
\text{ccwf} \triangleq \lambda f : \tau_1 \rightarrow \tau_2. \lambda k : \tau_2 \text{ cont}. \text{letcc}(\tau_1 \text{ cont})(\text{ret.throw}(\tau_1 \text{ cont})(f(\text{letcc}(\tau_1)(\text{r.throw}(\tau_1)(r; \text{ret})); k))
\]

How does this function work? Given \(f : \tau_1 \rightarrow \tau_2\) and \(k : \tau_2 \text{ cont}\), let’s consider what would happen if we threw some value \(e : \tau_1\) to the continuation \(\text{ccwf} f k : \tau_1 \text{ cont}\). First, we push the
throw onto the stack. (For our purposes, it doesn’t matter what type we give the throw.)

$$
\epsilon \mapsto \epsilon; \text{throw}\{\ldots\}(e; \text{ccwf } f \ k)
$$

Now we evaluate ccwf $f \ k$. After stepping through the application to $f$ and $k$, we save the current continuation ($\epsilon; \text{throw}\{\ldots\}(e; -)$) in the variable $\tau$ (which we’ll continue to write as $\text{ret}$ for sake of space). We then begin computing a value of type $\tau_2$ which we will eventually throw to $k$.

$$
\mapsto^* \epsilon; \text{throw}\{\ldots\}(e; -); \text{throw}\{\tau_2\}(-; k) \mapsto f(\text{letcc}\{\tau_1\}(r; \text{throw}\{\tau_1\}(r; \text{ret})))
$$

Assuming $f$ is a value, we push an application frame onto the stack. We again save the current continuation, which at this point expects a value of type $\tau_1$, in the variable $r$.

$$
\mapsto^* \epsilon; \text{throw}\{\ldots\}(e; -); \text{throw}\{\tau_2\}(-; k); f(-) \mapsto \text{letcc}\{\tau_1\}(r; \text{throw}\{\tau_1\}(r; \text{ret}))
$$

Finally, we throw $r$ to the continuation $\text{ret}$. The current stack is erased and replaced with the stack stored in $\text{ret}$, which was $\epsilon; \text{throw}\{\tau_1\}(e; -)$.

$$
\mapsto^* \epsilon; \text{throw}\{\ldots\}(e; -) \mapsto r
$$

Since $r$ is a value, we execute the throw at the top of the stack. It replaces the stack with $r$, which is $\epsilon; \text{throw}\{\ldots\}(e; -); \text{throw}\{\tau_2\}(-; k); f(-)$, and continues by evaluating $e$.

$$
\mapsto^* \epsilon; \text{throw}\{\ldots\}(e; -); \text{throw}\{\tau_2\}(-; k); f(-) \mapsto e
$$

Let’s say $f(e)$ evaluates to some value $v$. After said evaluation takes place, we execute the throw at the top of the stack, which throws $v$ to $k$, leaving us in the state

$$
\mapsto^* k \mapsto v
$$

In the end, then, throwing a value $e$ to (ccwf $f \ k$) amounts to throwing $f(e)$ to $k$.

**Task 3** Define programs with the following types. You may use ccwf in your definitions.

1. lem : $\tau + \tau$ cont
2. dne : $\tau$ cont cont $\rightarrow$ $\tau$
3. cps : $(\tau_1 \rightarrow \tau_2) \rightarrow (\tau_1 \text{ cont} + \tau_2)$

(Notice: if we interpret these types as propositions by treating $(-)$ cont as logical negation $\neg(-)$, these are tautologies of classical propositional logic!)

**Solution:**

1. lem $\triangleq$ letcc{$\tau + \tau$ cont}{k. R ∘ (ccwf $\lambda y: \tau. L \cdot y$) $k$})
2. dne $\triangleq$ $\lambda k:\tau$ cont cont. letcc{$\tau$}{x. throw{$\tau$ cont}{x; k}}
3. cps $\triangleq$ $\lambda f:\tau_1 \rightarrow \tau_2$. letcc{$\tau_1$ cont + $\tau_2$}{x. L ∘ (ccwf $\lambda y:\tau_1. R \cdot f(y)$) $x$})

**Task 4** Take $\tau = \text{int}$ in the previous task, and consider the following expression $e : \text{int}$ defined using your implementation of lemm.

$$
e \triangleq \text{case lemm} \{ \\
L \cdot x \mapsto 2 * x; \\
R \cdot c \mapsto \text{throw}{\text{int}}(6; c) \\
\}
$$

What is the result of evaluating $\epsilon \mapsto e$? You don’t have to write out the stack machine steps, but give an informal explanation of the evaluation process.
Solution: The result is 12. When \texttt{lem} is evaluated, it saves the current continuation in a variable \( k : \texttt{int} + \texttt{int cont} \), then returns \( R \cdot (\texttt{ccwf} \; (\texttt{lyy} \cdot L \cdot y_0 \cdot k)) \). The case therefore passes to the right branch, with \( e = \texttt{ccwf} \; (\texttt{lyy} \cdot L \cdot y_0 \cdot k) \). As demonstrated in the discussion of \texttt{ccwf} above, throwing \( 6 \) to \( c \) amounts to throwing \( L \cdot 6 \) to \( k \). We thus return to the original case statement, but this time matching against \( L \cdot 6 \). This time, the case passes to the left branch with \( x = 6 \), and thus returns \( 2 \cdot 6 \), which steps to 12.

### 2.2 Translating Continuations

In this section, we will show how to translate programs in a language \( I \) with continuations into a language \( K \) without them. The theorem we prove will have the following form:

\textbf{Theorem 1} Fix a type \( \rho \in I \). There are translations \(||-|\), |−| from types in \( K \) to types in \( I \) and a translation \( \hat{\cdot} \) from well-typed terms in \( K \) to terms in \( I \), all defined in terms of \( \rho \). If \( \Gamma \vdash_K e : \tau \), then \( |\Gamma||\vdash_I \hat{e} : |\tau| \). (Here, \(|-|-|\) is extended to a translation of contexts by translating the type of each variable.)

Of course, the value of this theorem depends on how we define \(|-|-|, |−| \) and \( \hat{\cdot} \). (Our definition will satisfy a correctness theorem comparing the results of evaluating \( e \) and \( \hat{e} \), but we will not discuss this here.) Let’s by defining the translations of types \(|\tau|\) and \(|\tau|\). These are defined by mutual recursion. First, we have

\[ |\tau| \triangleq (|\tau|| \rightarrow \rho) \rightarrow \rho \]

The type \( \rho \) represents the type of the “final result.” A value of type \(|\tau|\) accepts a “\(|\tau|\) continuation,” a term which computes a \( \rho \) from a \(|\tau|\), and uses it to compute such a \( \rho \). \(|\tau||\) is defined inductively on the structure of \( \tau \). Let’s say that \( K \) and \( I \) support natural numbers, products, and functions. We define

\[
\begin{align*}
|\texttt{nat}| & \triangleq \texttt{nat} \\
|\tau_1 \times \tau_2| & \triangleq |\tau_1| \times |\tau_2| \\
|\tau \rightarrow \tau_1| & \triangleq |\tau_2| \rightarrow |\tau_1| \\
|\tau \texttt{cont}| & \triangleq |\tau| \rightarrow \rho
\end{align*}
\]

The translation of context \(|\Gamma|\) is simply given by translating the type of each variable. Now, we will given the translation of expressions. This is a type-directed translation – the translation of some expression \( e \) with \( \Gamma \vdash_K e : \tau \) is defined by induction on its typing derivation. We will specify it by defining a judgment \( \Gamma \vdash e : \tau \rightsquigarrow \hat{e} \), which expresses that \( \Gamma \vdash_K e : \tau \) translates to \( \hat{e} \) and has a case for each typing rule in \( K \). After giving the definition, we will show that \(|\Gamma||\vdash_I \hat{e} : |\tau|\). Let’s start with the rules for variables and natural numbers.

\[
\begin{align*}
\Gamma, x : \tau & \vdash x : \tau \rightsquigarrow \lambda k. k(x) & \text{(TR-VAR)} \\
\Gamma \vdash z : \texttt{nat} & \rightsquigarrow \lambda k. k(z) & \text{(TR-Z)} \\
\Gamma \vdash e : \texttt{nat} & \rightsquigarrow \hat{e} & \text{(TR-S)} \\
\Gamma \vdash e_0 : \tau & \rightsquigarrow \hat{e}_0 & \Gamma, x : \texttt{nat} \vdash e_1 : \tau \rightsquigarrow \hat{e}_1 & \text{(TR-IFZ)}
\end{align*}
\]

To understand these rules, remember that each translation \( \hat{e} \) should be an expression of type \(|\tau| = (|\tau|| \rightarrow \rho) \rightarrow \rho\), a function which takes a “continuation” and returns a result (a term of type \( \rho \)). It is important to distinguish \(|\tau||\) from \((|\tau|| \rightarrow \rho) \rightarrow \rho\); although there is an obvious embedding from the former into the latter, taking \( e \) to \( \lambda k. k(e) \), such a transformation is not reversible in general. In other words, while we might think of \( \hat{e} \) as a function that, given a
“continuation”  \( k : \|\tau\| \to \rho \), supplies “e” to \( k \), this is not always accurate (although it is true in the case of the rules \( \text{Tr-Var} \) and \( \text{Tr-Z} \)). For one thing, this would require translating \( e \) into a \( 1 \) term of type \( \|\tau\| \), which is not always possible. Moreover, \( \hat{e} \) can use \( k \) in other ways. We can more accurately say that \( \hat{e} : \|\tau\| \) will compute a \( \rho \) if we tell it how we would compute a \( \rho \) given a \( \|\tau\| \), but it may accomplish this in ways other than “feeding in \( e \).”

With this in mind, let’s go through the rules for \( \text{nat} \). The translation for \( z \) is simple: given a “continuation” \( k : \text{nat} \to \rho \), it simply invokes \( k \) on \( z \). For \( s(e) \), we start by translating \( e \) into \( \hat{e} \). After taking an argument “continuation” \( k : \text{nat} \to \rho \), we apply \( \hat{e} \) to \( \lambda x. k(s(x)) \), the composition \( k \circ s \). Put informally, we tell \( \hat{e} \) that we want to “use \( e \)” by first taking its successor and then continuing with \( k \). Finally, the rule for \( \text{ifz}(e; e_0; x; e_1) \) supplies the translation \( \hat{e} \) with the continuation \( \lambda y. \text{ifz}(y; \hat{e}_0 k; x; \hat{e}_1 k) \), which uses \( y : \text{nat} \) by checking if it is zero and continuing with either \( \hat{e}_0 k \) or \( \hat{e}_1 k \) as appropriate.

**Task 5** Define translation rules for the product type \( \tau_1 \times \tau_2 \) (i.e., for pairing and the two projections). Make sure your definitions have the correct types!

**Solution:**

\[
\Gamma \vdash e_1 : \tau_1 \rightsquigarrow \hat{e}_1 \quad \Gamma \vdash e_2 : \tau_2 \rightsquigarrow \hat{e}_2
\]

\[
\begin{aligned}
\Gamma &\vdash (e_1, e_2) : \tau_1 \times \tau_2 \rightsquigarrow \lambda k. \hat{e}_1(\lambda x. \hat{e}_2(\lambda y. k((x, y)))) & (\text{TR-PAIR}) \\
\Gamma &\vdash e : \tau_1 \times \tau_2 \rightsquigarrow \hat{e} & (\text{TR-PROJ)}
\end{aligned}
\]

The translation becomes more interesting at the function type.

\[
\Gamma, x : \tau_2 \vdash e : \tau_1 \rightsquigarrow \hat{e}
\]

\[
\Gamma \vdash (\lambda x : \tau_2 : e) : \tau_2 \to \tau_1 \rightsquigarrow \lambda k. k(\lambda x : \|\tau_2\|) \hat{e} & (\text{TR-LAM})
\]

Recall that \( \|\tau_2 \to \tau_1\| \equiv \|\tau_1\| \to \|\tau_1\| \). If our translation has the right type behavior, then \( \|\Gamma\|, x : \|\tau_2\| \vdash \hat{e} : \|\tau_1\| \). Thus, \( \lambda x. \hat{e} \) has type \( \|\tau_2 \to \tau_1\| \), so we can supply it to the continuation \( k : \|\tau_2 \to \tau_1\| \to \rho \). The key here is that hypotheses are translated with \( \|\cdot\| \) and conclusions with \( |-| \), so it is natural to translate functions, which internalize a hypothetical, with \( \|\tau_2 \to \tau_1\| \equiv \|\tau_2\| \to \|\tau_1\| \).

**Task 6** Give a translation rule for function application. For sake of intuition, you may find it useful to note the following: if we expand the definition of \( \|\tau_2 \to \tau_1\| \) another step as \( \|\tau_2\| \to (\|\tau_1\| \to \rho) \to \rho \), we see that a translated function takes an argument of type \( \|\tau_2\| \) and a “return address” continuation which specifies how to continue with the result of type \( \|\tau_1\| \).

**Solution:**

\[
\Gamma \vdash e_1 : (\tau_2 \to \tau_1) \rightsquigarrow \hat{e}_1 \quad \Gamma \vdash e_2 : \tau_2 \rightsquigarrow \hat{e}_2
\]

\[
\begin{aligned}
\Gamma &\vdash e_1 e_2 : \tau_1 \rightsquigarrow \lambda k. \hat{e}_1(\lambda f : \|\tau_2\| \to \|\tau_1\|. \hat{e}_2(\lambda y : \|\tau_2\|. fyk)) & (\text{TR-APP})
\end{aligned}
\]

Finally, we come to continuations.

**Task 7** Give translation rules for \( \text{letcc}\{\tau\}(x.e) \) and \( \text{throw}\{\tau\}(e_1; e_2) \). These are actually quite simple!

**Solution:**

\[
\Gamma, x : \tau \vdash e : \tau \rightsquigarrow \hat{e}
\]

\[
\begin{aligned}
\Gamma &\vdash \text{letcc}\{\tau\}(x.e) : \tau \rightsquigarrow \lambda k. ((k/x) \hat{e}) k & (\text{TR-LETCC}) \\
\Gamma &\vdash e_1 : \tau \rightsquigarrow \hat{e}_1 \quad \Gamma &\vdash e_2 : \tau \rightsquigarrow \hat{e}_2
\end{aligned}
\]

\[
\begin{aligned}
\Gamma &\vdash \text{throw}\{\tau\}(e_1; e_2) : \tau' \rightsquigarrow \hat{e}_2 \hat{e}_1 & (\text{TR-THROW})
\end{aligned}
\]
This is enough to cover any program we would write in K, but there is a form of expression arising in execution which we haven’t handled – the term cont(k) where k is a stack. In order to handle this case (and in order to state a correctness of translation result with respect to evaluation), we’d have to define a translation of stack frames. We won’t pursue this here.
