

Clock Recovery When to sample voltage? Synchronized sender and receiver clocks Need easily detectible event at both ends Signal transitions help resync sender and receiver Need frequent transitions to prevent clock skew SONET XOR's bit sequence to ensure frequent transitions

4B/5B Encoding

- Data coded as symbols of 5 line bits => 4 data bits, so 100 Mbps uses 125 MHz.
 - · Uses less frequency space than Manchester encoding
- Encoding ensures no more than 3 consecutive 0's
- Uses NRZI to encode resulting sequence
- 16 data symbols, 8 control symbols
 - · Data symbols: 4 data bits
 - Control symbols: idle, begin frame, etc.
- · Example: FDDI.

4B/5B Encoding					
	Data	Code	Data	Code	
	0000 0001 0010 0011 0100 0101 0110 0111	11110 01001 10100 10101 01010 01011 01110 01111	1000 1001 1010 1011 1100 1101 1110 1111	10010 10011 10110 10111 11010 11011 11100 11101	
15-441 © C	MII 2010				14

Other Encodings

- 8B/10B: Fiber Channel and Gigabit Ethernet
- 64B/66B: 10 Gbit Ethernet
- B8ZS: T1 signaling (bit stuffing)

Things to Remember

- · Encoding necessary for clocking
- · Lots of approaches
- Rule of thumb:
 - Little bandwidth → complex encoding
 - Lots of bandwidth → simple encoding

15

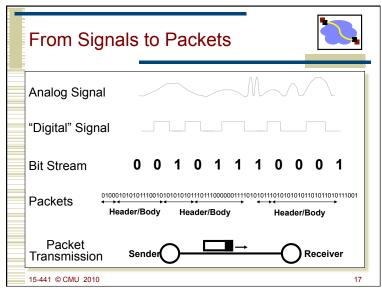

Where we are

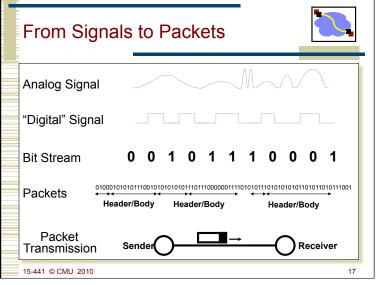

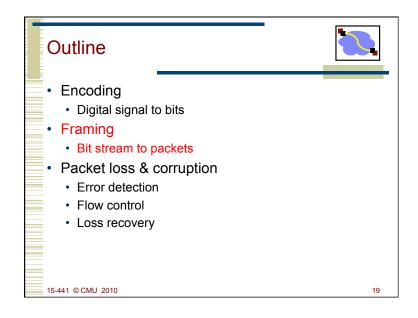

- We can send strings of bits
- We can keep the transmitter and receiver clock synchronized
- What next?

10

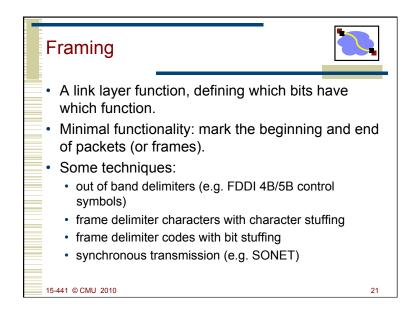

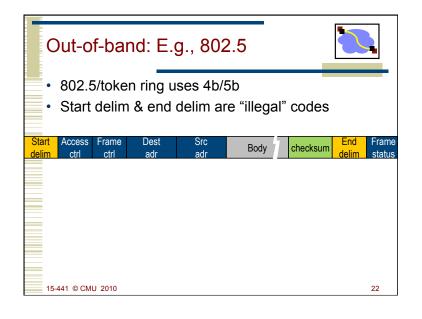

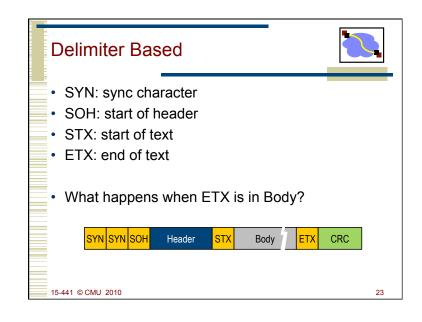

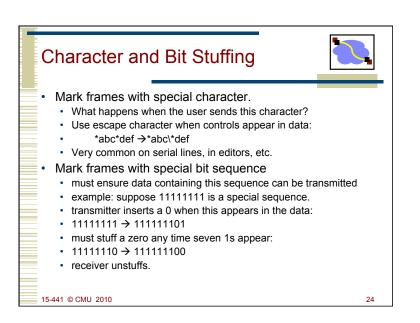

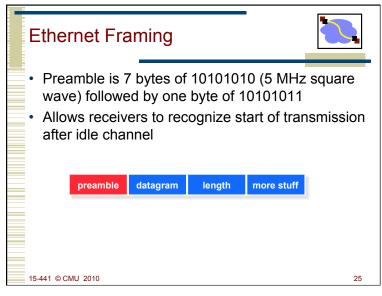

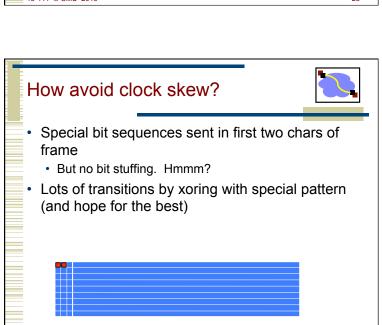

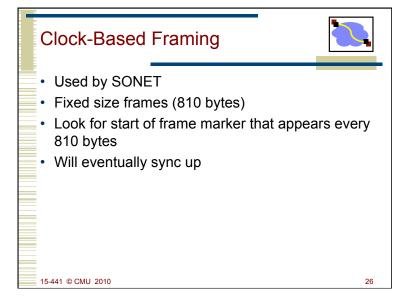

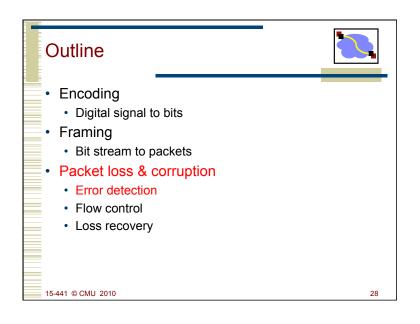

15-441 © CMU 2010

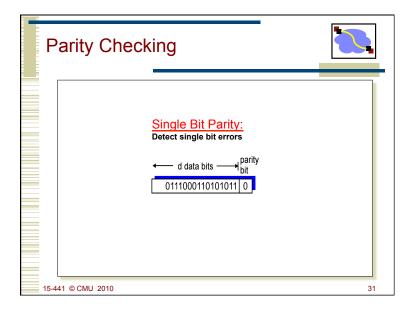

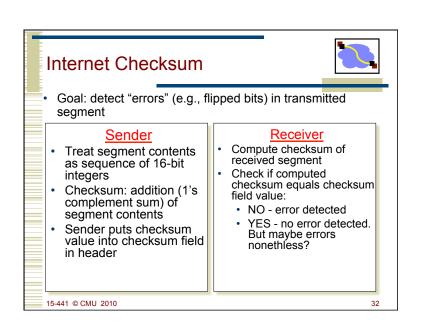

Transmission process may introduce errors into a message. Single bit errors versus burst errors Detection: Requires a convention that some messages are invalid Hence requires extra bits An (n,k) code has codewords of n bits with k data bits and r = (n-k) redundant check bits Correction Forward error correction: many related code words map to the same data word Detect errors and retry transmission

29

15-441 © CMU 2010

Error Detection • EDC= Error Detection and Correction bits (redundancy) • D = Data protected by error checking, may include header fields • Error detection not 100% reliable! · Protocol may miss some errors, but rarely · Larger EDC field yields better detection and correction datagram datagram all bits in D' OK detected ←d data bits— EDC EDC' () bit-error prone link (15-441 © CMU 2010

Basic Concept: Hamming Distance

- · Hamming distance of two bit strings = number of bit positions in which they differ.
- · If the valid words of a code have minimum Hamming distance D, then D-1 bit errors can be detected.
- If the valid words of a code have minimum Hamming distance D, then [(D-1)/2] bit errors can be corrected.

HD=3

1 0 1 1 0

1 1 0 1 0

Examples

- A (4,3) parity code has D=2:
 - 0001 0010 0100 0111 1000 1011 1101 1110
 - (last bit is binary sum of previous 3, inverted "odd parity")
- A (7,4) code with D=3 (2ED, 1EC):
 - 0000000 0001101 0010111 0011010
 - 0100011 0101110 0110100 0111001
 - 1000110 1001011 1010001 1011100
 - 1100101 1101000 1110010 1111111
- 1001111 corrects to 1001011
- Note the inherent risk in correction; consider a 2-bit error resulting in $1001011 \rightarrow 1111011$.
- There are formulas to calculate the number of extra bits that are needed for a certain D.

Cyclic Redundancy Codes (ČRC)

- · Commonly used codes that have good error detection properties.
 - Can catch many error combinations with a small number of redundant bits
- Based on division of polynomials.
 - · Errors can be viewed as adding terms to the polynomial
 - · Should be unlikely that the division will still work
- Can be implemented very efficiently in hardware.
- Examples:
 - CRC-32: Ethernet
 - CRC-8, CRC-10, CRC-32: ATM

15-441 © CMU 2010

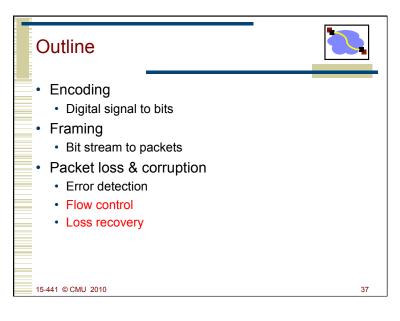

CRC: Basic idea

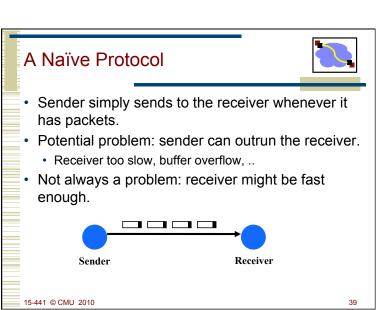

Treat bit strings as polynomials:
 1 0 1 1 1

- Sender and Receiver agree on a divisor polynomial of degree k
- Message of M bits → send M+k bits
- No errors if M+k is divisible by divisor polynomial
- If you pick the right divisor you can:
 - Detect all 1 & 2-bit errors
 - Any odd number of errors
 - All Burst errors of less than k bits
 - Some burst errors >= k bits

Link Flow Control and Error Recovery Dealing with receiver overflow: flow control. Dealing with packet loss and corruption: error control. Meta-comment: these issues are relevant at many layers. Link layer: sender and receiver attached to the same "wire" End-to-end: transmission control protocol (TCP) - sender and receiver are the end points of a connection How can we implement flow control? "You may send" (windows, stop-and-wait, etc.) "Please shut up" (source quench, 802.3x pause frames, etc.) Where are each of these appropriate?

15-441 © CMU 2010

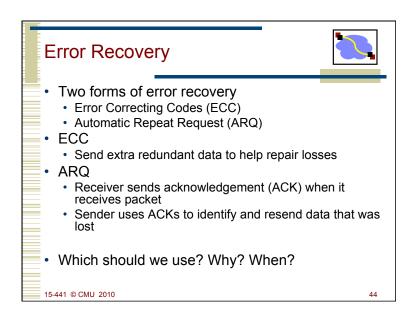

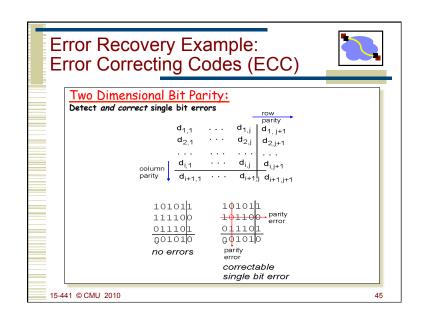

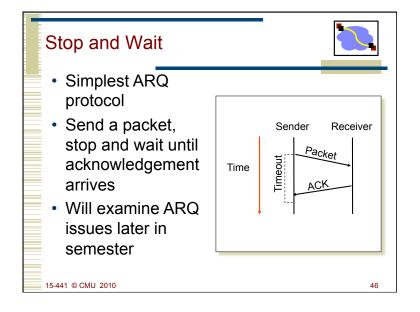

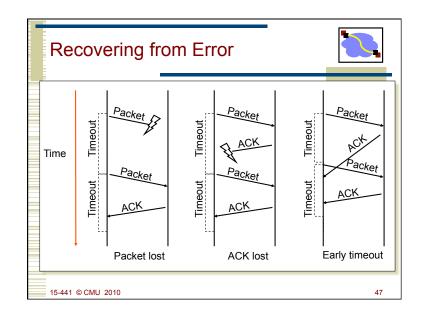

15-441 © CMU 2010

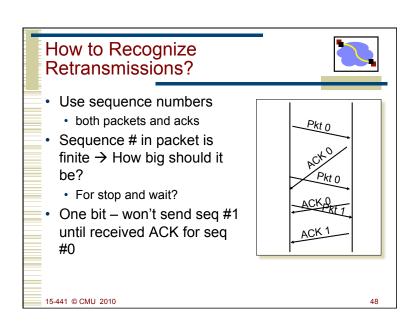

Stop and wait flow control results in poor throughput for long-delay paths: packet size/ roundtrip-time. Solution: receiver provides sender with a window that it can fill with packets. The window is backed up by buffer space on receiver. Receiver acknowledges the a packet every time a packet is consumed and a buffer is freed.

Issues with Window-based Protocol

- Receiver window size: # of out-of-sequence packets that the receiver can receive
- Sender window size: # of total outstanding packets that sender can send without acknowledged
- How to deal with sequence number wrap around?

49

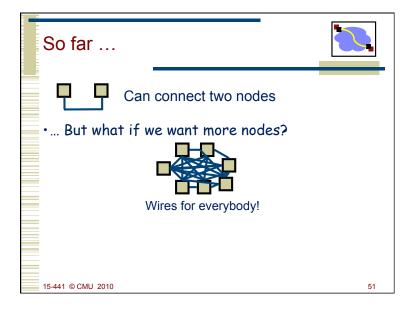

What is Used in Practice?

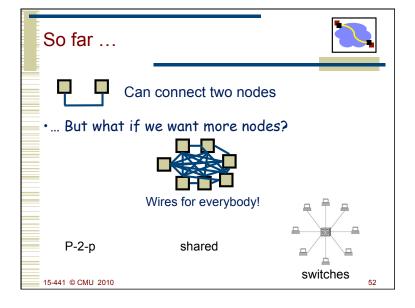

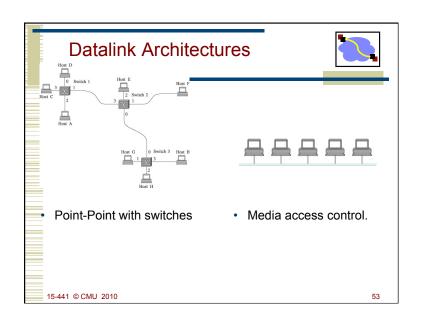

- · No flow or error control.
- E.g. regular Ethernet, just uses CRC for error detection
- · Flow control only.
 - E.g. Gigabit Ethernet
- Flow and error control.
 - E.g. X.25 (older connection-based service at 64 Kbs that guarantees reliable in order delivery of data)

Clock Based Framing: SONET

- SONET is the Synchronous Optical Network standard for data transport over optical fiber.
- One of the design goals was to be backwards compatible with many older telco standards.
- Beside minimal framing functionality, it provides many other functions:
 - operation, administration and maintenance (OAM) communications
 - synchronization
 - · multiplexing of lower rate signals
 - · multiplexing for higher rates
- In otherwords, really complicated!

15-441 © CMU 2010

. |

Standardization History

- Process was started by divestiture in 1984.
 - Multiple telephone companies building their own infrastructure
- SONET concepts originally developed by Bellcore.
- First standardized by ANSI T1X1 group for US.
- · Later by CCITT and developed its own version.
- SONET/SDH standards approved in 1988.

15-441 © CMU 2010

56

A Word about Data Rates

- · Bandwidth of telephone channel is under 4KHz, so when digitizing:
 - 8000 samples/sec * 8 bits = 64Kbits/second
- · Common data rates supported by telcos in North America:
 - Modem: rate improved over the years
 - T1/DS1: 24 voice channels plus 1 bit per sample (24 * 8 + 1) * 8000 = 1.544 Mbits/second
 - T3/DS3: 28 T1 channels:

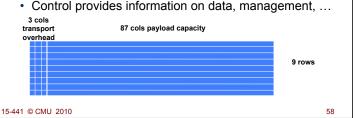

7 * 4 * 1.544 = 44.736 Mbits/second

15-441 © CMU 2010

Synchronous Data Transfer

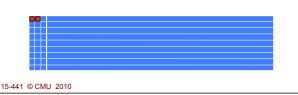

- · Sender and receiver are always synchronized.
 - Frame boundaries are recognized based on the clock
 - No need to continuously look for special bit sequences
- SONET frames contain room for control and data.
 - · Data frame multiplexes bytes from many users
 - Control provides information on data, management, ...

How avoid clock skew?

- · Special bit sequences sent in first two chars of frame
 - But no bit stuffing. Hmmm?
- Lots of transitions by xoring with special pattern (and hope for the best)

SONET Framing

- Base channel is STS-1 (Synchronous Transport System).
 - Takes 125 µsec and corresponds to 51.84 Mbps
 - 1 byte/frame corresponds to a 64 Kbs channel (voice)
 - Transmitted on an OC-1 optical carrier (fiber link)
- Standard ways of supporting slower and faster channels.
 - · Support both old standards and future (higher) data rates
