Reinforcement Learning

[Sutton and Barto 1981; Samuel 1957; ...]

\[ V^*(s) = \mathbb{E}[r_t + \gamma r_{t+1} + \gamma^2 r_{t+2} + \ldots] \]
Outline

• Learning control strategies
  – Credit assignment and delayed reward
  – Discounted rewards

• Markov Decision Processes
  – Solving a known MDP

• Online learning of control strategies
  – When next-state function is known: value function $V^*(s)$
  – When next-state function unknown: learning $Q^*(s,a)$

• Role in modeling reward learning in animals
Reinforcement Learning Problem

Agent: $S \rightarrow A$

Environment

$s_0 \xrightarrow{a_0} s_1 \xrightarrow{a_1} s_2 \xrightarrow{a_2} ...$

Goal: Learn to choose actions that maximize

$r_0 + \gamma r_1 + \gamma^2 r_2 + ...$, where $0 \leq \gamma < 1$
Markov Decision Process

• Set of states \( S \)
• Set of actions \( A \)
• At each time, agent observes state \( s_t \in S \), then chooses action \( a_t \in A \)
• Then receives reward \( r_t \), and state changes to \( s_{t+1} \)
• Markov assumption: \( P(s_{t+1} \mid s_t, a_t, s_{t-1}, a_{t-1}, \ldots) = P(s_{t+1} \mid s_t, a_t) \)
• Also assume \( P(r_t \mid s_t, a_t, s_{t-1}, a_{t-1}, \ldots) = P(r_t \mid s_t, a_t) \)

• The task: learn a policy \( \pi: S \to A \) for choosing actions that maximizes
  \[ E[r_t + \gamma r_{t+1} + \gamma^2 r_{t+2} + \ldots] \]
  \[ 0 < \gamma \leq 1 \]
HMM, Markov Process, Markov Decision Process

\[ \pi^* = \arg \max_{\pi} E \left[ R_t + \gamma R_{t+1} + \gamma^2 R_{t+2} + \ldots \right] \]

\[ P(C_{t+1} | S_t) \]
HMM, Markov Process, Markov Decision Process

[Diagram showing the relationships between HMM, MDP, and their components, including states, actions, and rewards.]
Reinforcement Learning Task for Autonomous Agent

Execute actions in environment, observe results, and
• Learn control policy $\pi: S \rightarrow A$ that maximizes $\sum_{t=0}^{\infty} \gamma^t E[r_t]$ from every state $s \in S$
• Where $0 < \lambda \cdot 1$ is the discount factor for future rewards

Note:
• Function to be learned is $\pi: S \rightarrow A$
• But training examples of the form $< s,a >, r >$
• Available training experience is not input-output pairs of the function to be learned!
Value Function for each Policy

• Given a policy \( \pi : S \rightarrow A \), define

\[
V^\pi(s) = E\left[ \sum_{t=0}^{\infty} \gamma^t r_t \right]
\]
assuming actions are chosen according to \( \pi \)

• Then we want the policy \( \pi^* \) where

\[
\pi^* = \arg \max_{\pi} V^\pi(s), \quad (\forall s)
\]

• For any MDP, such a policy exists

• We’ll write \( V^*(s) = V^{\pi^*}(s) \)

• Note if we have \( V^*(s) \) and \( P(s_{t+1}|s_t, a) \), we can compute \( \pi^*(s) \)
Value Function – what are the $V^\pi(s)$ values?

$$V^\pi(s) = E[\sum_{t=0}^{\infty} \gamma^t r_t]$$

Suppose $\gamma$ is shown by circled action from each state

Suppose $\gamma = 0.9$

$$V^\pi(s) = \sqrt{V^{\pi}(s)} + \gamma V^\pi(s)$$

$r(s, a)$ (immediate reward)
Value Function – what are the $V^\pi(s)$ values?

$$V^\pi(s) = E\left[ \sum_{t=0}^{\infty} \gamma^t r_t \right]$$

Suppose it is shown by circled action from each state.

Suppose $\gamma = 0.9$

$r(s, a) \text{ (immediate reward)}$
Value Function – what are the $V^*(s)$ values?

\[ V^\pi(s) = E[\sum_{t=0}^{\infty} \gamma^t r_t] \]

\[ \hat{V}^\pi \equiv V^* \]

Optimal policy

\[ r(s, a) \] (immediate reward)
Immediate rewards $r(s, a)$

State values $V^*(s)$

State-action values $Q^*(s, a)$

$r(s, a)$ (immediate reward) values

$Q(s, a)$ values

$V^*(s)$ values

One optimal policy
Recursive definition for \( V^*(S) \)

\[
V^*(s) = E\left[ \sum_{t=0}^{\infty} \gamma^t r_t \right] \quad \text{assuming actions are chosen according to the optimal policy, } \pi^*
\]

\[
V^*(s_1) = E[r(s_1, a_1)] + E[\gamma r(s_2, a_2)] + E[\gamma^2 r(s_3, a_3)] + \ldots
\]

\[
V^*(s_1) = E[r(s_1, a_1)] + \gamma E_{s_2|s_1, a_1}[V^*(s_2)]
\]

\[
V^*(s) = E[r(s, \pi^*(s))] + \gamma E_{P(s'|s, \pi^*(s))}[V^*(s')]
\]
Value Iteration for learning $V^*$ : assumes $P(S_{t+1}|S_t, A)$ known

Initialize $V(s)$ arbitrarily

Loop until policy good enough

Loop for $s$ in $S$

   Loop for $a$ in $A$

      $Q(s, a) \leftarrow r(s, a) + \gamma \sum_{s' \in S} P(s'|s, a)V(s')$

   $V(s) \leftarrow \max_a Q(s, a)$

End loop

End loop

$V(s)$ converges to $V^*(s)$.

Same alg works if we randomly traverse the environment, as long as visit every transition repeatedly.
Value Iteration

Interestingly, value iteration works even if we randomly traverse the environment instead of looping through each state and action methodically

• but we must still visit each state infinitely often on an infinite run
• For details: [Bertsekas 1989]
• Implications: online learning as agent randomly roams

If max (over states) difference between two successive value function estimates is less that $\varepsilon$, then the value of the greedy policy differs from the optimal policy by no more than

$$\frac{2\varepsilon \gamma}{1 - \gamma}$$
So far: learning optimal policy when we know $P(s_t | s_{t-1}, a_{t-1})$

What if we don’t?
Immediate rewards $r(s,a)$

State values $V^*(s)$

State-action values $Q^*(s,a)$

$$V^*(s) = E[r(s, \pi^*(s))] + \gamma E_{s'|s,\pi^*(s)}[V^*(s')]$$

$Q^*(s,a)$ (immediate reward) values

$V^*(s)$ values

One optimal policy

Tom Mitchell, April 2008
Q learning

Define new function, closely related to \( V^* \)

\[
V^*(s) = E[r(s, \pi^*(s))] + \gamma E_{s'}|s, \pi^*(s) [V^*(s')] \\
Q(s, a) = E[r(s, a)] + \gamma E_{s'}|s, a [V^*(s')] 
\]

If agent knows \( Q(s,a) \), it can choose optimal action without knowing \( P(s_{t+1}|s_t,a) \)!

\[
\pi^*(s) = \arg \max_a Q(s, a) \quad V^*(s) = \max_a Q(s, a) 
\]

And, it can learn \( Q \) without knowing \( P(s_{t+1}|s_t,a) \)
Define new function very similar to $V^*$

$$Q(s, a) \equiv r(s, a) + \gamma V^*(\delta(s, a))$$

If agent learns $Q$, it can choose optimal action even without knowing $\delta$!

$$\pi^*(s) = \argmax_a [r(s, a) + \gamma V^*(\delta(s, a))]$$

$$\pi^*(s) = \argmax_a Q(s, a)$$

$Q$ is the evaluation function the agent will learn.
Training Rule to Learn $Q$

Note $Q$ and $V^*$ closely related:

$$V^*(s) = \max_{a'} Q(s, a')$$

Which allows us to write $Q$ recursively as

$$Q(s_t, a_t) = r(s_t, a_t) + \gamma V^*(\delta(s_t, a_t))$$
$$= r(s_t, a_t) + \gamma \max_{a'} Q(s_{t+1}, a')$$

Nice! Let $\hat{Q}$ denote learner’s current approximation to $Q$. Consider training rule

$$\hat{Q}(s, a) \leftarrow r + \gamma \max_{a'} \hat{Q}(s', a')$$

where $s'$ is the state resulting from applying action $a$ in state $s$
\textit{Q} Learning for Deterministic Worlds

\begin{itemize}
  \item For each $s, a$ initialize table entry $\hat{Q}(s, a) \leftarrow 0$
  \item Observe current state $s$
  \item Do forever:
    \begin{itemize}
      \item Select an action $a$ and execute it
      \item Receive immediate reward $r$
      \item Observe the new state $s'$
      \item Update the table entry for $\hat{Q}(s, a)$ as follows:
        \[ \hat{Q}(s, a) \leftarrow r + \gamma \max_{a'} \hat{Q}(s', a') \]
      \item $s \leftarrow s'$
    \end{itemize}
\end{itemize}
Updating $\hat{Q}$

$$\hat{Q}(s_1, a_{right}) \leftarrow r + \gamma \max_{a'} \hat{Q}(s_2, a')$$
$$\leftarrow 0 + 0.9 \max\{63, 81, 100\}$$
$$\leftarrow 90$$

notice if rewards non-negative, then

$$(\forall s, a, n) \quad \hat{Q}_{n+1}(s, a) \geq \hat{Q}_n(s, a)$$

and

$$(\forall s, a, n) \quad 0 \leq \hat{Q}_n(s, a) \leq Q(s, a)$$
قاء $\hat{Q}$ converges to $Q$. Consider case of deterministic world where see each $\langle s, a \rangle$ visited infinitely often.

**Proof:** Define a full interval to be an interval during which each $\langle s, a \rangle$ is visited. During each full interval the largest error in $\hat{Q}$ table is reduced by factor of $\gamma$

Let $\hat{Q}_n$ be table after $n$ updates, and $\Delta_n$ be the maximum error in $\hat{Q}_n$; that is

$$\Delta_n = \max_{s,a} |\hat{Q}_n(s,a) - Q(s,a)|$$

For any table entry $\hat{Q}_n(s,a)$ updated on iteration $n + 1$, the error in the revised estimate $\hat{Q}_{n+1}(s,a)$ is

$$|\hat{Q}_{n+1}(s,a) - Q(s,a)| = |(r + \gamma \max_{a'} \hat{Q}_n(s', a')) \\
- (r + \gamma \max_{a'} Q(s', a'))|$$

$$= \gamma |\max_{a'} \hat{Q}_n(s', a') - \max_{a'} Q(s', a')|$$

$$\leq \gamma \max_{a'} |\hat{Q}_n(s', a') - Q(s', a')|$$

$$\leq \gamma \max_{s'',a'} |\hat{Q}_n(s'', a') - Q(s'', a')|$$

$$|\hat{Q}_{n+1}(s,a) - Q(s,a)| \leq \gamma \Delta_n$$

Use general fact:

$$\max_{a} |f_1(a) - \max_{a} f_2(a)| \leq \max_{a} |f_1(a) - f_2(a)|$$
Nondeterministic Case

$Q$ learning generalizes to nondeterministic worlds

Alter training rule to

$$\hat{Q}_n(s, a) \leftarrow (1 - \alpha_n) \hat{Q}_{n-1}(s, a) + \alpha_n [r + \max_{a'} \hat{Q}_{n-1}(s', a')]$$

where

$$\alpha_n = \frac{1}{1 + visits_n(s, a)}$$

Can still prove convergence of $\hat{Q}$ to $Q$ [Watkins and Dayan, 1992]
Temporal Difference Learning

$Q$ learning: reduce discrepancy between successive $Q$ estimates

One step time difference:

$$Q^{(1)}(s_t, a_t) \equiv r_t + \gamma \max_a \hat{Q}(s_{t+1}, a)$$

Why not two steps?

$$Q^{(2)}(s_t, a_t) \equiv r_t + \gamma r_{t+1} + \gamma^2 \max_a \hat{Q}(s_{t+2}, a)$$

Or $n$?

$$Q^{(n)}(s_t, a_t) \equiv r_t + \gamma r_{t+1} + \cdots + \gamma^{n-1} r_{t+n-1} + \gamma^n \max_a \hat{Q}(s_{t+n}, a)$$

Blend all of these:

$$Q^\lambda(s_t, a_t) \equiv (1-\lambda) \left[ Q^{(1)}(s_t, a_t) + \lambda Q^{(2)}(s_t, a_t) + \lambda^2 Q^{(3)}(s_t, a_t) \right]$$
Temporal Difference Learning

\[ Q^\lambda(s_t, a_t) \equiv (1-\lambda) \left[ Q^{(1)}(s_t, a_t) + \lambda Q^{(2)}(s_t, a_t) + \lambda^2 Q^{(3)}(s_t, a_t) \right] \]

Equivalent expression:

\[ Q^\lambda(s_t, a_t) = r_t + \gamma \left[ (1 - \lambda) \max_a \hat{Q}(s_t, a_t) \right. \]
\[ \left. + \lambda \ Q^\lambda(s_{t+1}, a_{t+1}) \right] \]

TD(\lambda) algorithm uses above training rule

- Sometimes converges faster than Q learning
- converges for learning \( V^* \) for any \( 0 \leq \lambda \leq 1 \) (Dayan, 1992)
- Tesauro’s TD-Gammon uses this algorithm
Subtleties and Ongoing Research

- Replace $\hat{Q}$ table with neural net or other generalizer
- Handle case where state only partially observable
- Design optimal exploration strategies
- Extend to continuous action, state
- Learn and use $\delta : S \times A \rightarrow S$
- Relationship to dynamic programming
