1 Introduction

The nefarious Dr. Evil has planted a slew of “binary bombs” on our machines. A binary bomb is a program that consists of a sequence of phases. Each phase expects you to type a particular string on stdin. If you type the correct string, then the phase is defused and the bomb proceeds to the next phase. Otherwise, the bomb explodes by printing "BOOM!!!" and then terminating. The bomb is defused when every phase has been defused.

There are too many bombs for us to deal with, so we are giving each of you a bomb to defuse. Your mission, which you have no choice but to accept, is to defuse your bomb before the due date. Good luck, and welcome to the bomb squad!

Step 1: Get Your Bomb

Each student will attempt to defuse their own personalized bomb. Each bomb is a Linux binary executable file that has been compiled from a C program. To obtain your bomb, send mail to

    bomb@bluegill.cmcl.cs.cmu.edu

with the following Subject line:

    bomb request spring03 user@host

where user@host is your email address. The bomb daemon will assign you a unique bomb and then mail it to the email address on the Subject line. For example, if your Andrew login ID is foo, then your Subject line should be:
bomb request spring03 foo@andrew

If you accidently delete your bomb, simply request another and we’ll sort out the duplicate assignments later on when we grade the lab.

**Step 2: Defuse Your Bomb**

Once you have received your bomb from the bomb daemon, save it in a secure directory such as `~/213hw/L2`. Your job is to defuse the bomb.

You can use many tools to help you with this; please look at the hints section for some tips and ideas. The best way is to use your favorite debugger to step through the disassembled binary.

Each time your bomb explodes it notifies the staff, and you lose 1/4 point (up to a max of 10 points) in the final score for the lab. So there are consequences to exploding the bomb. You must be careful!

Each phase is worth 10 points, for a total of 60 points.

The phases get progressively harder to defuse, but the expertise you gain as you move from phase to phase should offset this difficulty. However, the last phase will challenge even the best students, so please don’t wait until the last minute to start.

The bomb ignores blank input lines. If you run your bomb with a command line argument, for example,

```
linux> ./bomb psol.txt
```

then it will read the input lines from `psol.txt` until it reaches EOF (end of file), and then switch over to `stdin`. In a moment of weakness, Dr. Evil added this feature so you don’t have to keep retyping the solutions to phases you have already defused.

To avoid accidently detonating the bomb, you will need to learn how to single-step through the assembly code and how to set breakpoints. You will also need to learn how to inspect both the registers and the memory states. One of the nice side-effects of doing the lab is that you will get very good at using a debugger. This is a crucial skill that will pay big dividends the rest of your career.

**Logistics**

As usual, this is an individual assignment.

Any clarifications and revisions to the assignment will be posted on the class bboard and Web page.

You should do the assignment on the fish machines. In fact, there is a rumor that Dr. Evil really is evil, and the bomb will always blow up if run elsewhere. There are several other tamper-proofing devices built into the bomb as well, or so they say.
Hand-In

There is no explicit hand-in. The bomb will notify your instructor automatically after you have successfully defused it. You can keep track of how you (and the other students) are doing by looking at

www.cs.cmu.edu/afs/cs/academic/class/15213-s03/www/daemons/bombstats.html

This web page is updated continuously to show the progress of each student.

Hints (Please read this!)

There are many ways of defusing your bomb. You can examine it in great detail without ever running the program, and figure out exactly what it does. This is a useful technique, but it not always easy to do. You can also run it under a debugger, watch what it does step by step, and use this information to defuse it. This is probably the fastest way of defusing it.

We do make one request, please do not use brute force! You could write a program that will try every possible key to find the right one. But this is no good for several reasons:

- You lose 1/4 point (up to a max of 10 points) every time you guess incorrectly and the bomb explodes.
- Every time you guess wrong, a message is sent to the staff. You could very quickly saturate the network with these messages, and cause the system administrators to revoke your computer access.
- We haven’t told you how long the strings are, nor have we told you what characters are in them. Even if you made the (wrong) assumptions that they all are less than 80 characters long and only contain letters, then you will have $26^{80}$ guesses for each phase. This will take a very long time to run, and you will not get the answer before the assignment is due.

There are many tools which are designed to help you figure out both how programs work, and what is wrong when they don’t work. Here is a list of some of the tools you may find useful in analyzing your bomb, and hints on how to use them.

- **gdb**
  The GNU debugger, this is a command line debugger tool available on virtually every platform. You can trace through a program line by line, examine memory and registers, look at both the source code and assembly code (we are not giving you the source code for most of your bomb), set breakpoints, set memory watch points, and write scripts. Here are some tips for using **gdb**.
  - To keep the bomb from blowing up every time you type in a wrong input, you’ll want to learn how to set breakpoints.
  - The CS:APP Student Site
    csapp.cs.cmu.edu/public/students.html
    has a very handy single-page **gdb** summary.
– For other documentation, type “help” at the gdb command prompt, or type “man gdb”, or “info gdb” at a Unix prompt. Some people also like to run gdb under gdb-mode in emacs.

- **ddd**
  The Data Display Debugger ddd is a graphical front-end for command-line debuggers such as gdb.

- **objdump -t**
  This will print out the bomb’s symbol table. The symbol table includes the names of all functions and global variables in the bomb, the names of all the functions the bomb calls, and their addresses. You may learn something by looking at the function names!

- **objdump -d**
  Use this to disassemble all of the code in the bomb. You can also just look at individual functions. Reading the assembler code can tell you how the bomb works.

- **strings**
  This utility will display the printable strings in your bomb.

Looking for a particular tool? How about documentation? Don’t forget, the commands `apropos` and `man` are your friends. In particular, `man ascii` might come in useful. Also, the web may also be a treasure trove of information. If you get stumped, feel free to ask your TA for help.
