## On Raising A Number To A Power

### So Far We Have Seen:

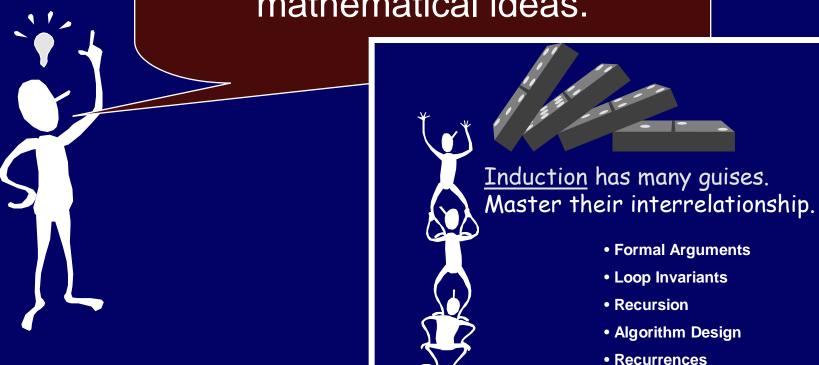

Don't let the representation choose you. CHOOSE THE REPRESENTATION!

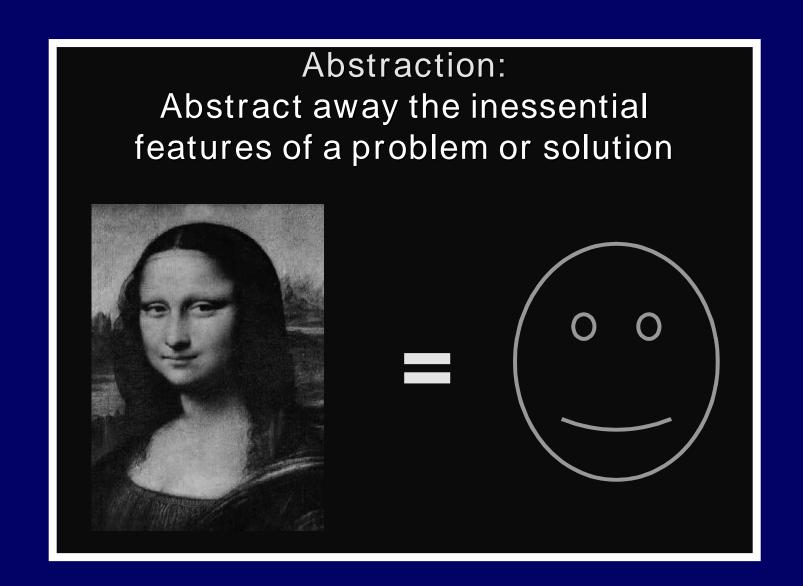

## 

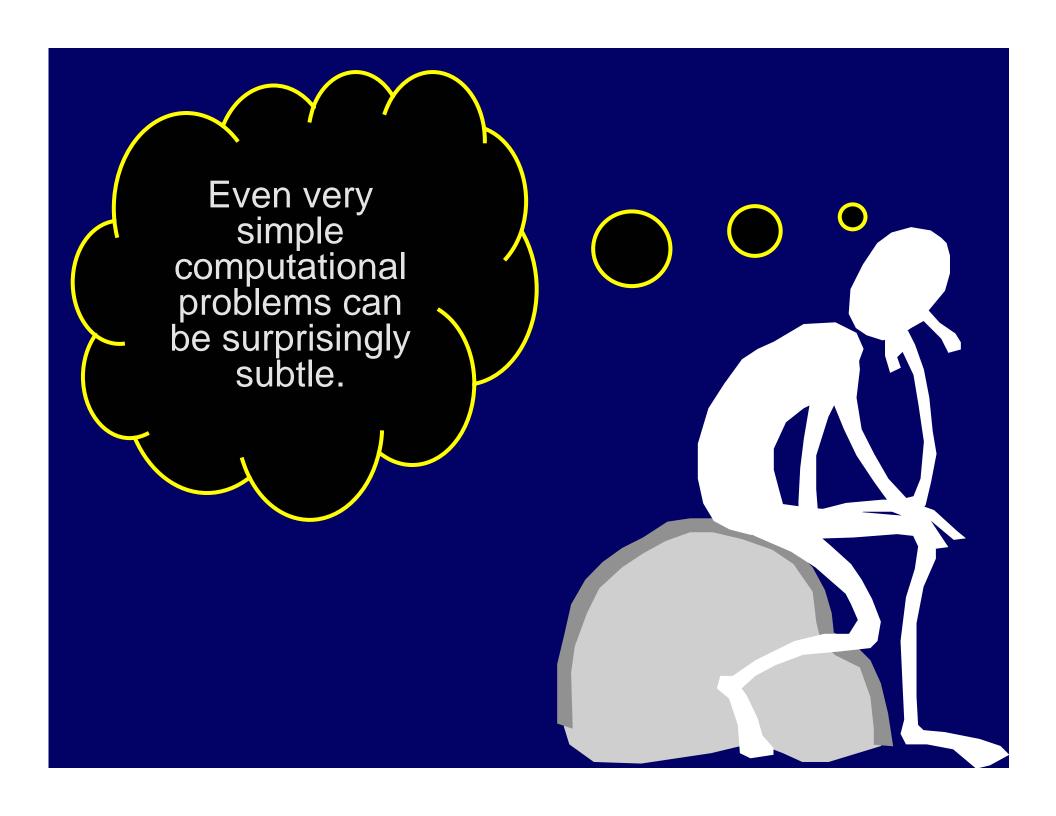

### So Far We Have Seen:

Induction is how we define and manipulate mathematical ideas.

### Let's Articulate A New One:

### Compiler Translation

A compiler must translate a high level language (e.g., C) with complex operations (e.g., exponentiation) into a lower level language (e.g., assembly) that can only support simpler operations (e.g., multiplication).

## b:=a8

This method costs only 3 multiplications. The savings are significant if b:=a<sup>8</sup> is executed often.

### General Version

Given a constant k, how do we implement b:=ak with the fewest number of multiplications?

# Powering By Repeated Multiplication

Input: a,n

Output:

A sequence starting with a, ending with a<sup>n</sup>, and such that each entry other than the first is the product of previous entries.

### Example

Input: a,5

Output:  $a, a^2, a^3, a^4, a^5$ 

or

Output:  $a, a^2, a^3, a^5$ 

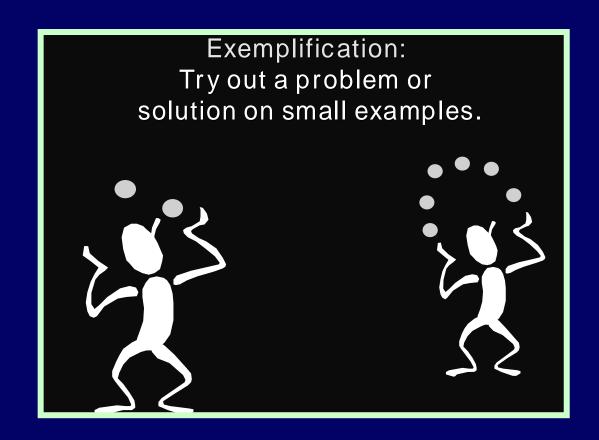

or

Output:  $a, a^2, a^4, a^5$ 

### Definition of M(n)

M(n) = The minimum number of multiplications required to produce an by repeated multiplication

# What is M(n)? Can we calculate it exactly? Can we approximate it?

### Some Very Small Examples

### What is M(1)?

- M(1) = 0 [a]
- What is M(0)?
  - M(0) is not clear how to define
- What is M(2)?
  - -M(2) = 1 [a, a<sup>2</sup>]

$$M(8) = ?$$

a,  $a^2$ ,  $a^4$ ,  $a^8$  is a way to make  $a^8$  in 3 multiplications. What does this tell us about the value of M(8)?

$$M(8) = ?$$

a,  $a^2$ ,  $a^4$ ,  $a^8$  is a way to make  $a^8$  in 3 multiplications. What does this tell us about the value of M(8)?

$$M(8) \leq 3$$

**Upper Bound** 

 $? \leq M(8) \leq 3$ 

Lower Bound

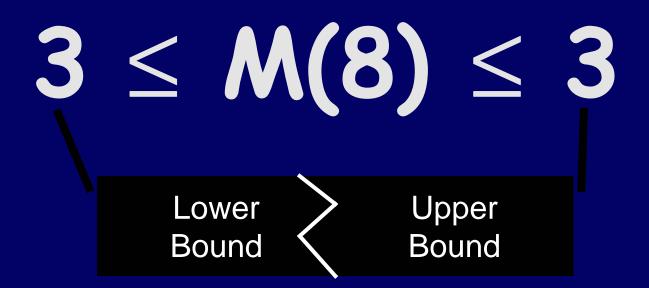

$$? \leq M(8) \leq 3$$

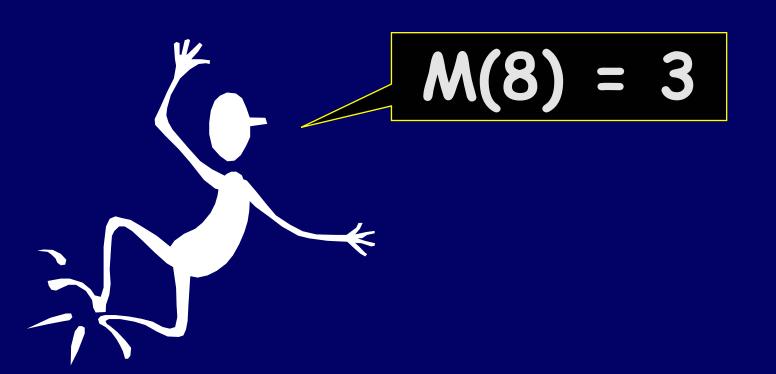

Lower Bound

$$3 \leq M(8)$$

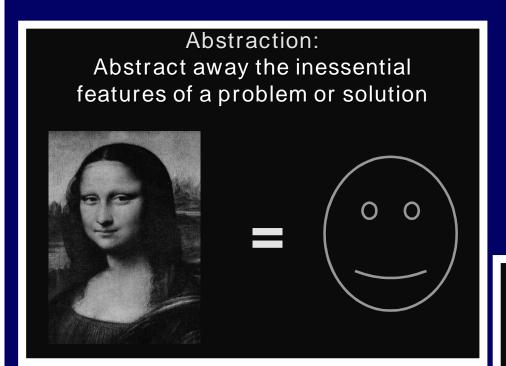

Exhaustive Search. There are only two sequences with 2 multiplications. Neither of them make 8:

 $a, a^2, a^3 \& a, a^2, a^4$ 

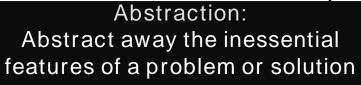

### Applying Two Ideas

# What is the more essential representation of M(n)?

Representation:
Understand the relationship between different representations of the same information or idea

1	
2	

## The a is a red herring.

### ax times ay is ax+y

Everything besides the exponent is inessential. This should be viewed as a problem of repeated addition, rather than repeated multiplication.

### Addition Chains

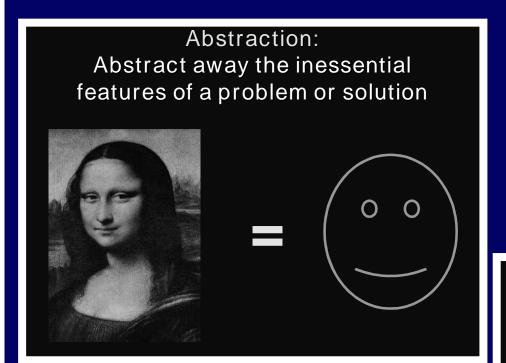

M(n) = Number of stages required to make n, where we start at 1 and in each subsequent stage we add two previously constructed numbers.

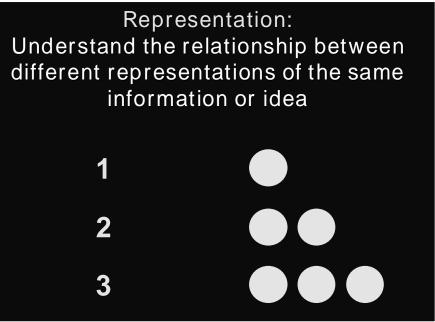

### Examples

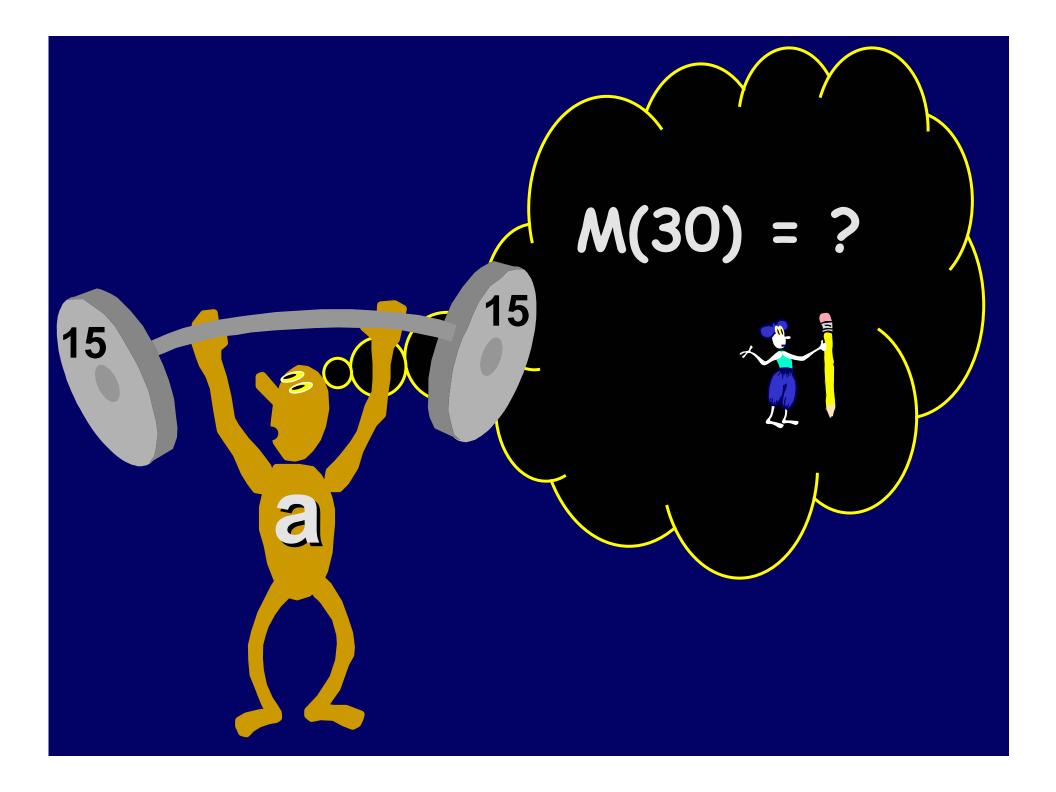

Addition Chain for 8: 1 2 3 5 8

Minimal Addition Chain for 8: 1248

### Addition Chains Are A Simpler To Represent The Original Problem

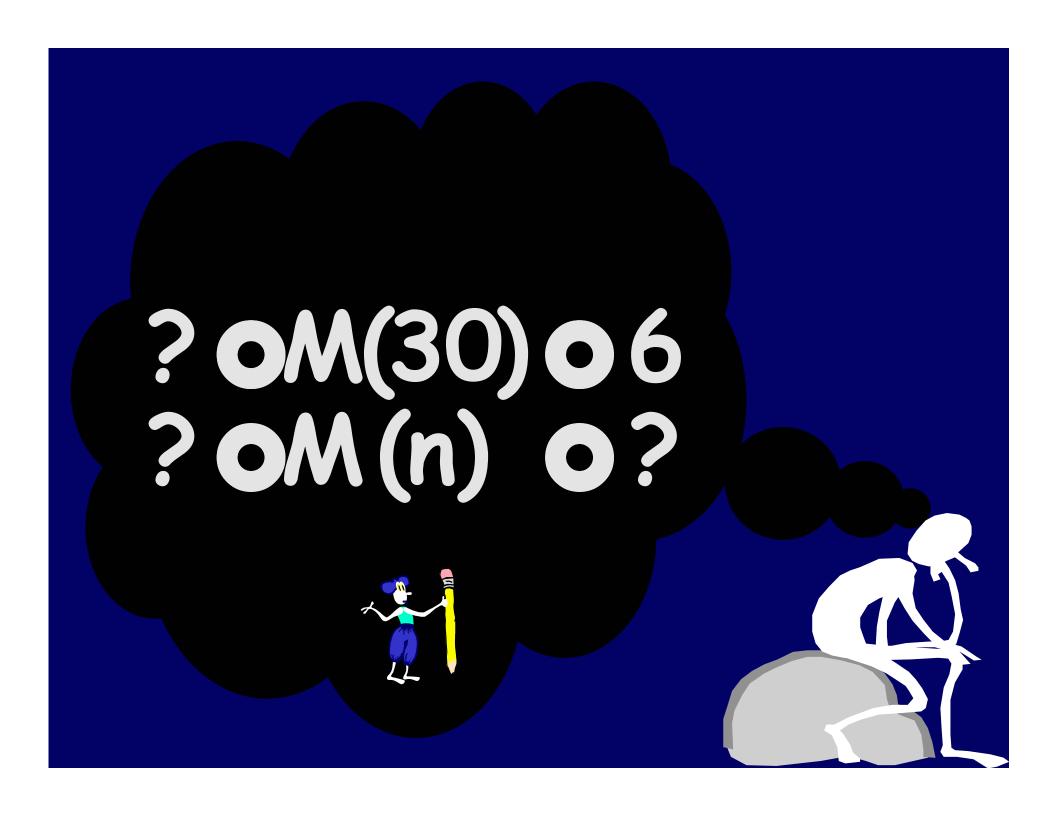

### Some Addition Chains For 30

1 2 4 8 16 24 28 30

1 2 4 5 10 20 30

1 2 3 5 10 15 30

1 2 4 8 10 20 30

### Binary Representation

Let  $B_n$  be the number of 1s in the binary representation of n. Ex:  $B_5 = 2$  since 101 is the binary representation of 5

Proposition:  $B_n \leq \lfloor \log_2(n) \rfloor + 1$ 

The length of the binary representation of n is bounded by this quantity.

### Binary Method Repeated Squaring Method Repeated Doubling Method

```
Phase I (Repeated Doubling)
For \lfloor \log_2 n \rfloor stages:

Add largest so far to itself (1, 2, 4, 8, 16, ...)
```

Phase II (Make n from bits and pieces)

Expand n in binary to see how n is the sum of  $B_n$  powers of 2. Use  $B_n$ -1 stages to make n from the powers of 2 created in phase I

Total Cost:  $\lfloor \log_2 n \rfloor + B_n - 1$ 

### Binary Method Applied To 30

	<u>Binary</u>
30	11110
Phase I	
1	1
2	10
4	100
8	1000
16	10000

Phase II: 6 14 30 (Cost: 7 additions)

## Rhind Papyrus (1650 BC) What is 30 times 5?

1 5

2 10

4 20

8 40

16 80

24 120

28 140

30 150

30 by a chain of 7:

1 2 4 8 16 24 28 30

Repeated doubling is the same as the Egyptian binary multiplication

# Rhind Papyrus (1650 BC) Actually used faster chain for 30\*5.

1 5

2 10

4 20

8 40

10 50

20 100

30 150

30 by a chain of 6:

1 2 4 8 10 20 30

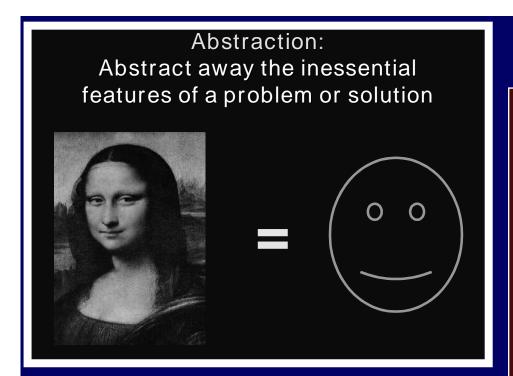

### The Egyptian Connection

A shortest addition chain for n gives a shortest method for the Egyptian approach to multiplying by the number n.

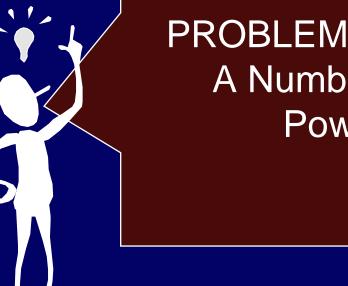

The fastest scribes would seek to know M(n) for commonly arising values of n.

 $M(n) \leq \lfloor \log_2 n \rfloor + B_n - 1 \leq 2 \lfloor \log_2 n \rfloor$ 

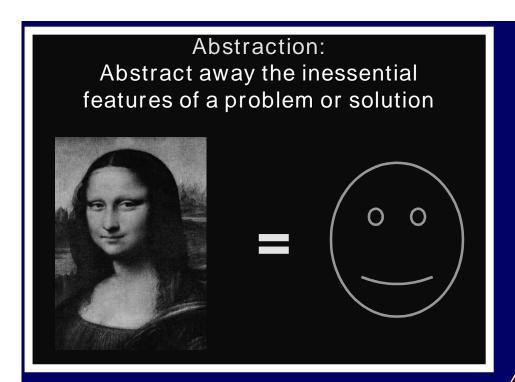

We saw that applying ABSTRACTION to the PROBLEM simplifies the issue.

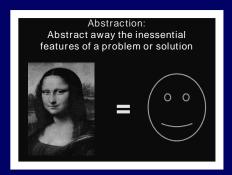

PROBLEM = Raising A Number To A Power.

What about ABSTRACTION to the SOLTUTION ?????

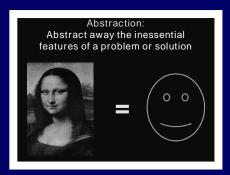

Let SOLUTION be the Repeated Squaring Algorithm.

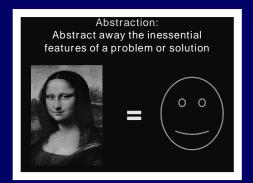

What features did our solution (RQA) actually make use of?

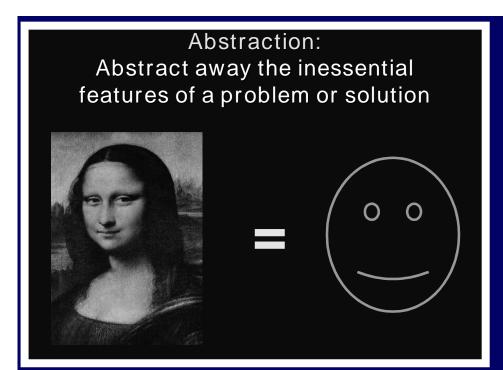

For example, does the RQA require the underlying objects to be numbers?

The repeated squaring method works for modular arithmetic and for raising a matrix to a power.

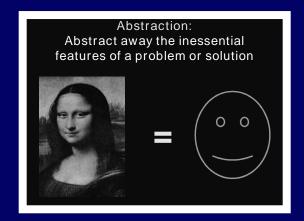

The repeated squaring method works for any notion of "multiplication" that is associative.

(a\*b)\*c = a\*(b\*c)  $a^k$  is well defined  $a^x * a^y = a^{x+y}$ 

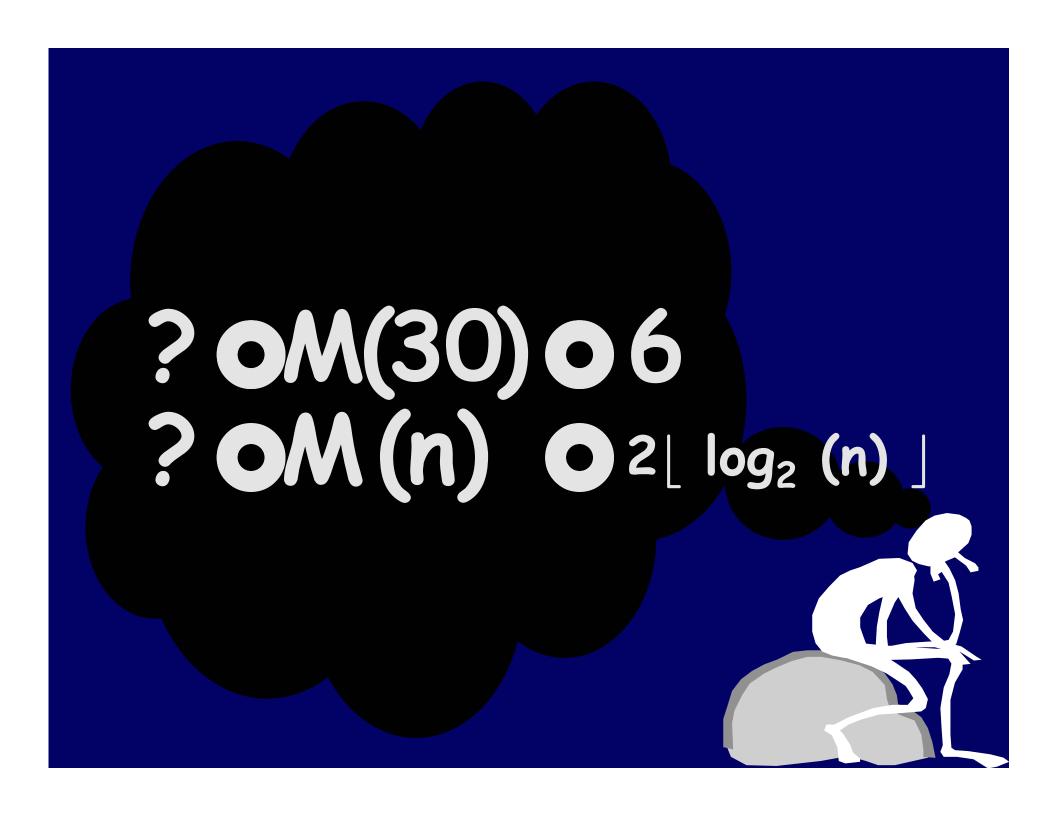

#### GENERALIZATION

Always yourself what your solution actually requires.

#### A Lower Bound Idea

You can't make any number bigger than  $2^n$  in n steps.

1 2 4 8 16 32 64 . . . Failure of Imagination?

#### Induction Proof

Theorem: For all  $n \ge 0$ , no n stage addition chain will contain a number greater than  $2^n$ 

Let  $S_k$  be the statement that no k stage addition chain will contain a number greater than  $2^k$ 

Base case: k=0.  $S_0$  is true since no chain can exceed  $2^0$  after 0 stages.

$$\forall k \geqslant 0$$
,  $S_k \Rightarrow S_{k+1}$ 

At stage k+1 we add two numbers from the previous stage. From  $S_k$  we know that they both are bounded by  $2^k$ . Hence, their sum is bounded by  $2^{k+1}$ . No number greater than  $2^{k+1}$  can be present by stage k+1.

# Proof By Invariant (Induction)

Invariant: All the numbers created by stage n, are less than or equal to  $2^n$ .

The invariant is true at the start.

Suppose we are at stage k. If the invariant is true, then the two numbers we decide to sum for stage k+1 are  $\leq 2^k$  and hence create a number less than or equal to  $2^{k+1}$ . The invariant is thus true at stage k+1.

### Change Of Variable

All numbers obtainable in m stages are bounded by  $2^m$ . Let m =  $log_2(n)$ .

Thus, All numbers obtainable in  $log_2(n)$  stages are bounded by n.

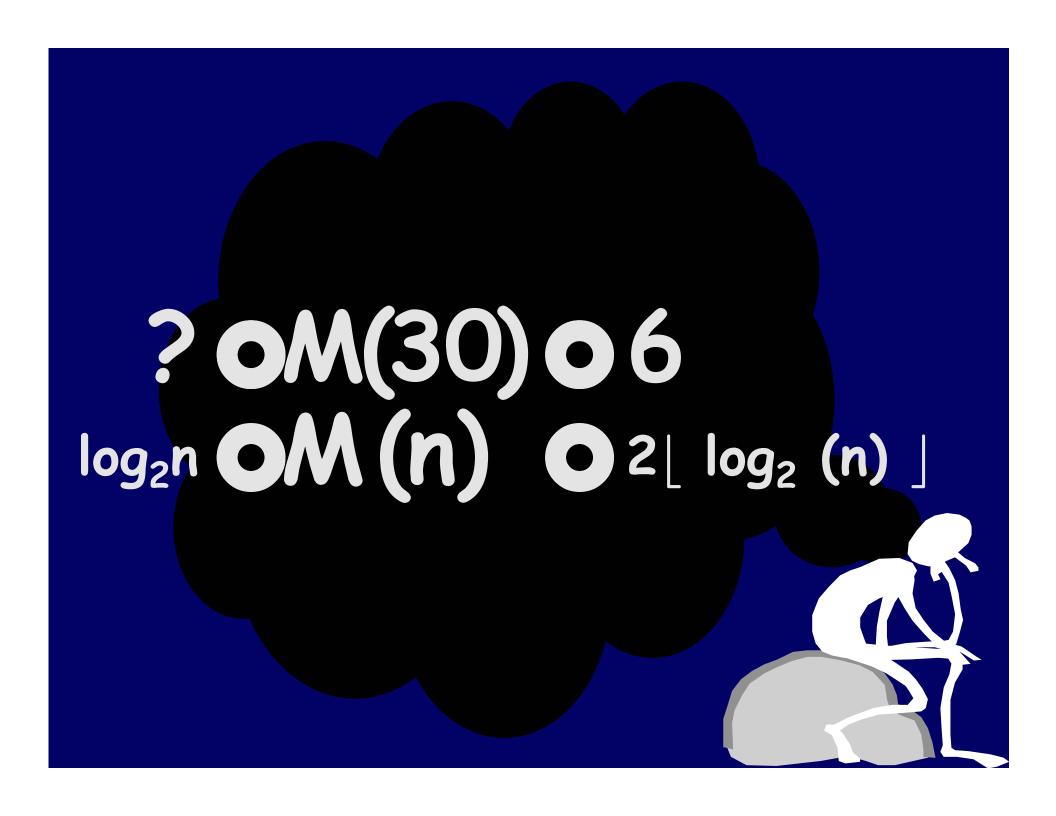

$$M(n) \ge \log_2(n)$$

In fact, 
$$M(n) \geq \lceil \log_2(n) \rceil$$

Theorem: 2<sup>i</sup> is the largest number that can be made in i stages, and can only be made by repeated doubling

Base i = 0 is clear.

To make anything as big as  $2^i$  requires having some X as big as  $2^{i-1}$  in i-1 stages. By I.H., we must have all the powers of 2 up to  $2^{i-1}$  at stage i-1. Hence, we can only double  $2^{i-1}$  at stage i. The theorem follows.

#### 5 < M(30)

Suppose that M(30)=5. At the last stage, we added two numbers  $x_1$  and  $x_2$  to get 30.

Without loss of generality (WLOG), we assume that  $x_1 \ge x_2$ .

Thus,  $x_1 \ge 15$ 

By doubling bound,  $x_1 \le 16$ 

But  $x_1$  can't be 16 since there is only one way to make 16 in 4 stages and it does not make 14 along the way.

Thus,  $x_1 = 15$  and M(15)=4

#### Suppose M(15) = 4

At stage 3, a number bigger than 7.5, but not more than 8 must have existed. There is only one sequence that gets 8 in 3 additions: 1 2 4 8

That sequence does not make 7 along the way and hence there is nothing to add to 8 to make 15 at the next stage.

Thus, M(15) > 4. CONTRADICTION.

$$M(30)=6$$

# M(30) = 6 $\log_2 n OM(n) O2[\log_2(n)]$

#### Rhind Papyrus (1650 BC)

1 5

2 10

4 20

8 40

10 50

20 100

30 150

30 = 1 2 4 8 10 20 30

## Factoring Bound

$$M(ab) \leq M(a)+M(b)$$

#### Factoring Bound

 $M(ab) \le M(a)+M(b)$ Proof:

- Construct a in M(a) additions
- Using a as a unit follow a construction method for b using M(b) additions. In other words, every time the construction of b refers to a number x, use the number a times x.

#### Example

$$45 = 5 * 9$$
 $M(5)=3$ 
 $M(9)=4$ 
 $M(45) \le 3+4$ 
 $M(45) \le 3+4$ 

### Corollary (Using Induction)

$$M(a_1a_2a_3...a_n) \leq M(a_1)+M(a_2)+...+M(a_n)$$

Proof: For n=1 the bound clearly holds. Assume it has been shown for up to n-1. Apply theorem using  $a = a_1 a_2 a_3 ... a_{n-1}$  and  $b = a_n$  to obtain:

$$M(a_1a_2a_3...a_n) \leq M(a_1a_2a_3...a_{n-1})+M(a_n)$$

By inductive assumption,

$$M(a_1a_2a_3...a_{n-1}) \leq M(a_1)+M(a_2)+...+M(a_{n-1})$$

#### More Corollaries

Corollary:  $M(a^k) \leq kM(a)$ 

Corollary: 
$$M(p_1^{\alpha_1}p_2^{\alpha_2}p_3^{\alpha_3}...p_n^{\alpha_n})$$

$$\leq \alpha_1 M(p_1) + \alpha_2 M(p_2) + ... + \alpha_n M(p_n)$$

Does equality hold?

$$M(33) < M(3) + M(11)$$

$$M(3) = 2$$
 [1 2 3]  
 $M(11) = 5$  [1 2 3 5 10 11]  
 $M(3) + M(11) = 7$ 

$$M(33) = 6$$
 [1 2 4 8 16 32 33]

The conjecture of equality fails. There have been many nice conjectures. . . .

## Conjecture: M(2n) = M(n) + 1(A. Goulard)

A fastest way to an even number is to make half that number and then double it.

Proof given in 1895 by E. de Jonquieres in L'Intermediere Des Mathematiques volume 2, pages 125-126

FALSE! M(191)=M(382)=11 Furthermore, there are infinitely many such examples.

# Open Problem

Is there an n such that:

M(2n) < M(n)

# Conjecture

Each stage might as well consist of adding the largest number so far to one of the other numbers.

First Counter-example: 12,509 [1 2 4 8 16 17 32 64 128 256 512 1024 1041 2082 4164 8328 8345 12509]

# Open Problem

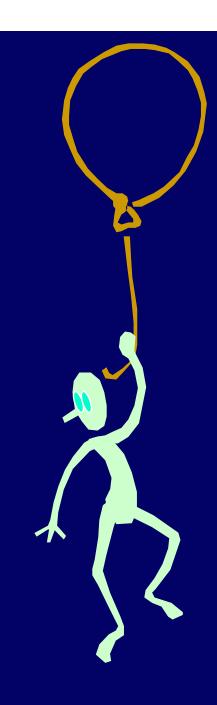

Prove or disprove the Scholz-Brauer Conjecture:

$$M(2^{n}-1) \leq n - 1 + B_{n}$$

(The bound that follows from this lecture is too weak:  $M(2^n-1) \le 2n-1$ )

## High Level Point

Don't underestimate "simple" problems. Some "simple" mysteries have endured for thousand of years.

Raising To A Power

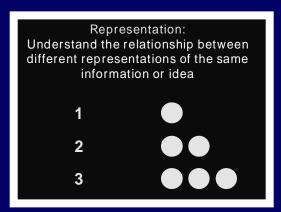

Minimal Addition Chain

Lower and Upper Bounds

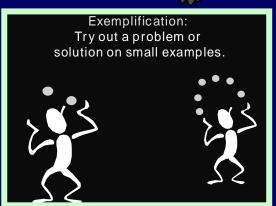

RQA [Repeated Squaring Algorithm]
RQA works for ANY binary operator
