

Dynamic Memory Allocation: Advanced Concepts

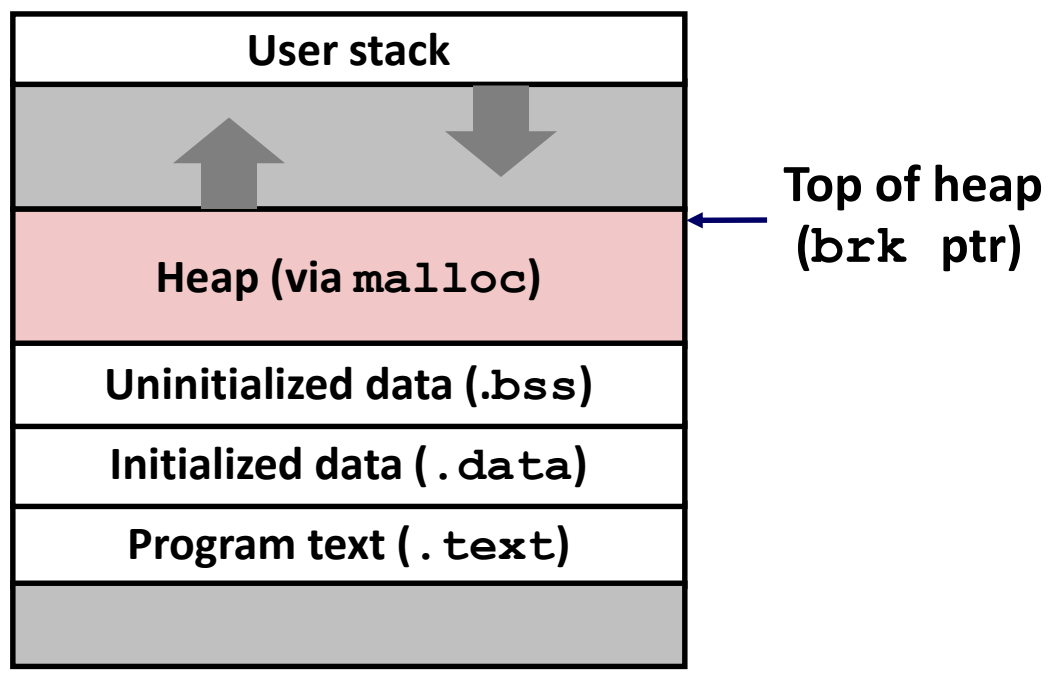

15-213: Introduction to Computer Systems
20th Lecture, June 25, 2019

Instructor:

Brian Railing

Dynamic Memory Allocation

- Programmers use *dynamic memory allocators* (such as `malloc`) to acquire VM at run time.
 - For data structures whose size is only known at runtime.
- Dynamic memory allocators manage an area of process virtual memory known as the *heap*.

Last Lecture: Keeping Track of Free Blocks

- Method 1: *Implicit list* using length—links all blocks

- Method 2: *Explicit list* among the free blocks using pointers

- Method 3: *Segregated free list*
 - Different free lists for different size classes
- Method 4: *Blocks sorted by size*
 - Can use a balanced tree (e.g. Red-Black tree) with pointers within each free block, and the length used as a key

Summary: Implicit Lists

- **Implementation: very simple**
- **Allocate cost:**
 - linear time worst case
- **Free cost:**
 - constant time worst case
 - even with coalescing
- **Memory usage:**
 - will depend on placement policy
 - First-fit, next-fit or best-fit
- **Not used in practice for `malloc/free` because of linear-time allocation**
 - used in many special purpose applications
- **However, the concepts of splitting and boundary tag coalescing are general to *all* allocators**

Today

- **Explicit free lists**
- Segregated free lists
- Memory-related perils and pitfalls

Keeping Track of Free Blocks

- Method 1: *Implicit free list* using length—links all blocks

- Method 2: *Explicit free list* among the free blocks using pointers

- Method 3: *Segregated free list*
 - Different free lists for different size classes
- Method 4: *Blocks sorted by size*
 - Can use a balanced tree (e.g. Red-Black tree) with pointers within each free block, and the length used as a key

Explicit Free Lists

Allocated (as before)

Free

- **Maintain list(s) of *free* blocks, not *all* blocks**

- The “next” free block could be anywhere
 - So we need to store forward/back pointers, not just sizes
 - Still need boundary tags for coalescing
 - Luckily we track only free blocks, so we can use payload area

Explicit Free Lists

- Logically:

- Physically: blocks can be in any order

Allocating From Explicit Free Lists

conceptual graphic

Before

After

(with splitting)

Freeing With Explicit Free Lists

- ***Insertion policy:*** Where in the free list do you put a newly freed block?

- **Unordered**

- LIFO (last-in-first-out)
 - Insert freed block at the end of the free list
 - FIFO (first-in-first-out)
 - Insert freed block at the beginning of the free list
 - ***Pro:*** simple and efficient
 - ***Con:*** studies suggest fragmentation is higher than LIFO/FIFO

Aside: Premature Optimization

Don't!

- **Address-ordered**

- Insert freed block at the beginning of the free list

$addr(prev) < addr(curr) < addr(next)$

- ***Con:*** requires search
 - ***Pro:*** studies suggest fragmentation is lower than LIFO/FIFO

Freeing With Explicit Free Lists

- ***Insertion policy:*** Where in the free list do you put a newly freed block?
- **Unordered**
 - LIFO (last-in-first-out) policy
 - Insert freed block at the beginning of the free list
 - FIFO (first-in-first-out) policy
 - Insert freed block at the end of the free list
 - ***Pro:*** simple and constant time
 - ***Con:*** studies suggest fragmentation is worse than address ordered
- **Address-ordered policy**
 - Insert freed blocks so that free list blocks are always in address order:
 $addr(prev) < addr(curr) < addr(next)$
 - ***Con:*** requires search
 - ***Pro:*** studies suggest fragmentation is lower than LIFO/FIFO

Freeing With a LIFO Policy (Case 1)

conceptual graphic

- Insert the freed block at the root of the list

Freeing With a LIFO Policy (Case 2)

conceptual graphic

- Splice out successor block, coalesce both memory blocks and insert the new block at the root of the list

Freeing With a LIFO Policy (Case 3)

conceptual graphic

- Splice out predecessor block, coalesce both memory blocks, and insert the new block at the root of the list

Freeing With a LIFO Policy (Case 4)

conceptual graphic

- Splice out predecessor and successor blocks, coalesce all 3 memory blocks and insert the new block at the root of the list

Some Advice: An Implementation Trick

- **Use circular, doubly-linked list**
- **Support multiple approaches with single data structure**
- **First-fit vs. next-fit**
 - Either keep free pointer fixed or move as search list
- **LIFO vs. FIFO**
 - Insert as next block (LIFO), or previous block (FIFO)

Explicit List Summary

■ Comparison to implicit list:

- Allocate is linear time in number of *free* blocks instead of *all* blocks
 - *Much faster* when most of the memory is full
- Slightly more complicated allocate and free since needs to splice blocks in and out of the list
- Some extra space for the links (2 extra words needed for each block)
 - Does this increase internal fragmentation?

■ Most common use of linked lists is in conjunction with *segregated free lists*

- Keep multiple linked lists of different size classes, or possibly for different types of objects

Today

- **Explicit free lists**
- **Segregated free lists**
- **Memory-related perils and pitfalls**

Segregated List (Seglist) Allocators

- Each *size class* of blocks has its own free list

- Often have separate classes for each small size
- For larger sizes: One class for each two-power size

Seglist Allocator

- Given an array of free lists, each one for some size class

- To allocate a block of size n :
 - Search appropriate free list for block of size $m > n$
 - If an appropriate block is found:
 - Split block and place fragment on appropriate list (optional)
 - If no block is found, try next larger class
 - Repeat until block is found

- If no block is found:
 - Request additional heap memory from OS (using `sbrk()`)
 - Allocate block of n bytes from this new memory
 - Place remainder as a single free block in largest size class.

Seglist Allocator (cont.)

■ To free a block:

- Coalesce and place on appropriate list

■ Advantages of seglist allocators

- Higher throughput
 - log time for power-of-two size classes
- Better memory utilization
 - First-fit search of segregated free list approximates a best-fit search of entire heap.
 - Extreme case: Giving each block its own size class is equivalent to best-fit.

More Info on Allocators

- **D. Knuth, “*The Art of Computer Programming*”, 2nd edition, Addison Wesley, 1973**
 - The classic reference on dynamic storage allocation
- **Wilson et al, “*Dynamic Storage Allocation: A Survey and Critical Review*”, Proc. 1995 Int’l Workshop on Memory Management, Kinross, Scotland, Sept, 1995.**
 - Comprehensive survey
 - Available from CS:APP student site (csapp.cs.cmu.edu)

Today

- Explicit free lists
- Segregated free lists
- **Memory-related perils and pitfalls**

Memory-Related Perils and Pitfalls

- Dereferencing bad pointers
- Reading uninitialized memory
- Overwriting memory
- Referencing nonexistent variables
- Freeing blocks multiple times
- Referencing freed blocks
- Failing to free blocks

C operators

<i>Operators</i>		<i>Associativity</i>		
<code>()</code>	<code>[]</code>	<code>-></code>	<code>.</code>	left to right
<code>!</code>	<code>~</code>	<code>++</code>	<code>--</code>	right to left
<code>*</code>	<code>/</code>	<code>%</code>	<code>*</code>	left to right
<code>+</code>	<code>-</code>	<code>+</code>	<code>-</code>	left to right
<code><<</code>	<code>>></code>	<code><</code>	<code>></code>	left to right
<code><=</code>	<code>>=</code>	<code>==</code>	<code>!=</code>	left to right
<code>&</code>	<code>^</code>	<code>&&</code>	<code> </code>	left to right
<code> </code>	<code>?:</code>	<code>=</code>	<code>+=</code>	left to right
<code>&&</code>	<code> </code>	<code>-=</code>	<code>*=</code>	left to right
<code> </code>	<code>?:</code>	<code>/=</code>	<code>%=</code>	left to right
<code>?:</code>	<code>=</code>	<code>&=</code>	<code>^=</code>	left to right
<code>=</code>	<code>+=</code>	<code>-=</code>	<code>*=</code>	left to right
<code>/=</code>	<code>%=</code>	<code>&=</code>	<code>^=</code>	left to right
<code>!=</code>	<code><<=</code>	<code>>>=</code>		left to right
<code><<=</code>	<code>>>=</code>			left to right
<code>>>=</code>				left to right
<code>,</code>				left to right

- `->`, `()`, and `[]` have high precedence, with `*` and `&` just below
- Unary `+`, `-`, and `*` have higher precedence than binary forms

C Pointer Declarations: Test Yourself!

<code>int *p</code>	p is a pointer to int
<code>int *p[13]</code>	p is an array[13] of pointer to int
<code>int *(p[13])</code>	p is an array[13] of pointer to int
<code>int **p</code>	p is a pointer to a pointer to an int
<code>int (*p)[13]</code>	p is a pointer to an array[13] of int
<code>int *f()</code>	f is a function returning a pointer to int
<code>int (*f)()</code>	f is a pointer to a function returning int
<code>int (*(*f()) [13]) ()</code>	f is a function returning ptr to an array[13] of pointers to functions returning int
<code>int (*(*x[3]) ()) [5]</code>	x is an array[3] of pointers to functions returning pointers to array[5] of ints

Parsing: `int (*(*f()) [13]) ()`

`int (*(*f()) [13]) ()` `f`

`int (*(*f()) [13]) ()` `f is a function`

`int (*(*f()) [13]) ()` `f is a function
that returns a ptr`

`int (*(*f()) [13]) ()` `f is a a function
that returns a ptr to an
array of 13`

`int (*(*f()) [13]) ()` `f is a ptr to a function
that returns a ptr to an
array of 13 ptrs`

`int (*(*f()) [13]) ()` `f is a ptr to a function
that returns a ptr to an
array of 13 ptrs to function
returning an int`

C Pointer Declarations: Test Yourself!

<code>int *p</code>	p is a pointer to int
<code>int *p[13]</code>	p is an array[13] of pointer to int
<code>int *(p[13])</code>	p is an array[13] of pointer to int
<code>int **p</code>	p is a pointer to a pointer to an int
<code>int (*p)[13]</code>	p is a pointer to an array[13] of int
<code>int *f()</code>	f is a function returning a pointer to int
<code>int (*f)()</code>	f is a pointer to a function returning int
<code>int (*(*f()) [13]) ()</code>	f is a function returning ptr to an array[13] of pointers to functions returning int
<code>int (*(*x[3]) ()) [5]</code>	x is an array[3] of pointers to functions returning pointers to array[5] of ints

A better way: `int (* (*f ()) [13]) ()`

// pointer to a function returning an int

```
typedef int (*pfri) ();
```

// An array of thirteen pfri's

```
typedef pfri arr13pfri[13];
```

// pointer to an array of thirteen pfri's

```
typedef arr13pfri* ptrToArr;
```

// ptr to function returning a

// ptr to an array of 13 pointer's to functions which return ints

```
typedef ptrToArr (*pfrArr13fri) ();
```

Dereferencing Bad Pointers

■ The classic scanf bug

```
int val;  
  
...  
  
scanf ("%d", val);
```

Reading Uninitialized Memory

- Assuming that heap data is initialized to zero

```
/* return y = Ax */
int *matvec(int **A, int *x) {
    int *y = malloc(N*sizeof(int));
    int i, j;

    for (i=0; i<N; i++)
        for (j=0; j<N; j++)
            y[i] += A[i][j]*x[j];
    return y;
}
```

- Can avoid by using `calloc`

Overwriting Memory

- Allocating the (possibly) wrong sized object

```
int **p;  
  
p = malloc(N*sizeof(int));  
  
for (i=0; i<N; i++) {  
    p[i] = malloc(M*sizeof(int));  
}
```

- Can you spot the bug?

Overwriting Memory

■ Off-by-one errors

```
char **p;  
  
p = malloc(N*sizeof(char *));  
  
for (i=0; i<=N; i++) {  
    p[i] = malloc(M*sizeof(char));  
}
```

```
char *p;  
  
p = malloc(strlen(s));  
strcpy(p, s);
```

Overwriting Memory

- Not checking the max string size

```
char s[8];  
int i;  
  
gets(s); /* reads "123456789" from stdin */
```

- Basis for classic buffer overflow attacks

Overwriting Memory

- Misunderstanding pointer arithmetic

```
int *search(int *p, int val) {  
    while (p && *p != val)  
        p += sizeof(int);  
  
    return p;  
}
```

Overwriting Memory

- Referencing a pointer instead of the object it points to

```
int *BinheapDelete(int **binheap, int *size) {
    int *packet;
    packet = binheap[0];
    binheap[0] = binheap[*size - 1];
    *size--;
    Heapify(binheap, *size, 0);
    return(packet);
}
```

Operators

```
( ) [ ] -> . ++ -- * & (type) sizeof
! ~ ++ -- + - *
* / %
+ -
<< >>
< <= > >=
== !=
&
^
|
&&
||
?:
= += -= *= /= %= &= ^= != <<= >>=
,
```

Associativity

```
left to right
right to left
left to right
left to right
left to right
left to right
left to right
left to right
left to right
left to right
right to left
right to left
left to right
```

Referencing Nonexistent Variables

- Forgetting that local variables disappear when a function returns

```
int *foo () {  
    int val;  
  
    return &val;  
}
```

Freeing Blocks Multiple Times

- Nasty!

```
x = malloc(N*sizeof(int));  
    <manipulate x>  
free(x);  
  
y = malloc(M*sizeof(int));  
    <manipulate y>  
free(x);
```

Referencing Freed Blocks

■ Evil!

```
x = malloc(N*sizeof(int));  
  <manipulate x>  
free(x);  
  ...  
y = malloc(M*sizeof(int));  
for (i=0; i<M; i++)  
  y[i] = x[i]++;
```

Failing to Free Blocks (Memory Leaks)

- Slow, long-term killer!

```
foo() {  
    int *x = malloc(N*sizeof(int));  
    ...  
    return;  
}
```

Failing to Free Blocks (Memory Leaks)

■ Freeing only part of a data structure

```
struct list {
    int val;
    struct list *next;
};

foo() {
    struct list *head = malloc(sizeof(struct list));
    head->val = 0;
    head->next = NULL;
    <create and manipulate the rest of the list>
    ...
    free(head);
    return;
}
```

Dealing With Memory Bugs

■ Debugger: `gdb`

- Good for finding bad pointer dereferences
- Hard to detect the other memory bugs

■ Data structure consistency checker

- Runs silently, prints message only on error
- Use as a probe to zero in on error

■ Binary translator: `valgrind`

- Powerful debugging and analysis technique
- Rewrites text section of executable object file
- Checks each individual reference at runtime
 - Bad pointers, overwrites, refs outside of allocated block

■ `glibc malloc` contains checking code

- `setenv MALLOC_CHECK_ 3`
