Optimization III: Cache Memories

15-213/18-243: Introduction to Computer Systems

12th Lecture, 22 February 2010

Instructors:

Bill Nace and Gregory Kesden

The Exam

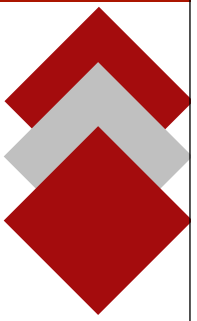
- **Tuesday, 2 March**
- **Closed book, closed notes, closed friend, open mind**
  - We will provide reference material
- **Quite unlike past exams**
- **Material from Lectures 1 - 9, Labs 1 & 2**
  - Representation of Integers, Floats
  - Machine code for control structures, procedures
    - Stack discipline
  - Layout of Arrays, Structs, Unions in memory
  - Floating point operations

Last Time

- **Program optimization**
  - Optimization blocker: Memory aliasing
  - One solution: Scalar replacement of array accesses that are reused

```
for (i = 0; i < n; i++) {
        b[i] = 0;
        for (j = 0; j < n; j++)
            b[i] += a[i*n + j];
    }
```

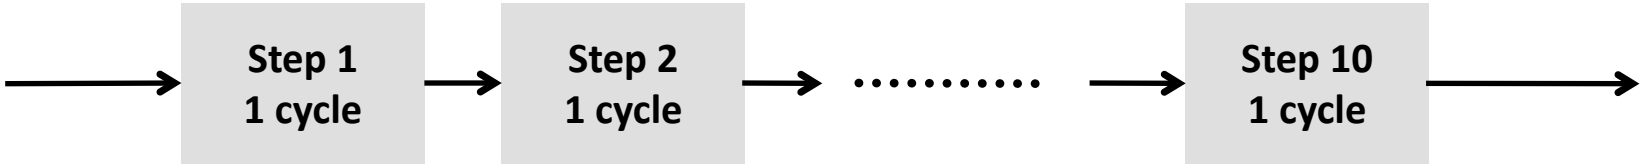
```
for (i = 0; i < n; i++) {
        double val = 0;
        for (j = 0; j < n; j++)
            val += a[i*n + j];
        b[i] = val;
    }
```



Last Time

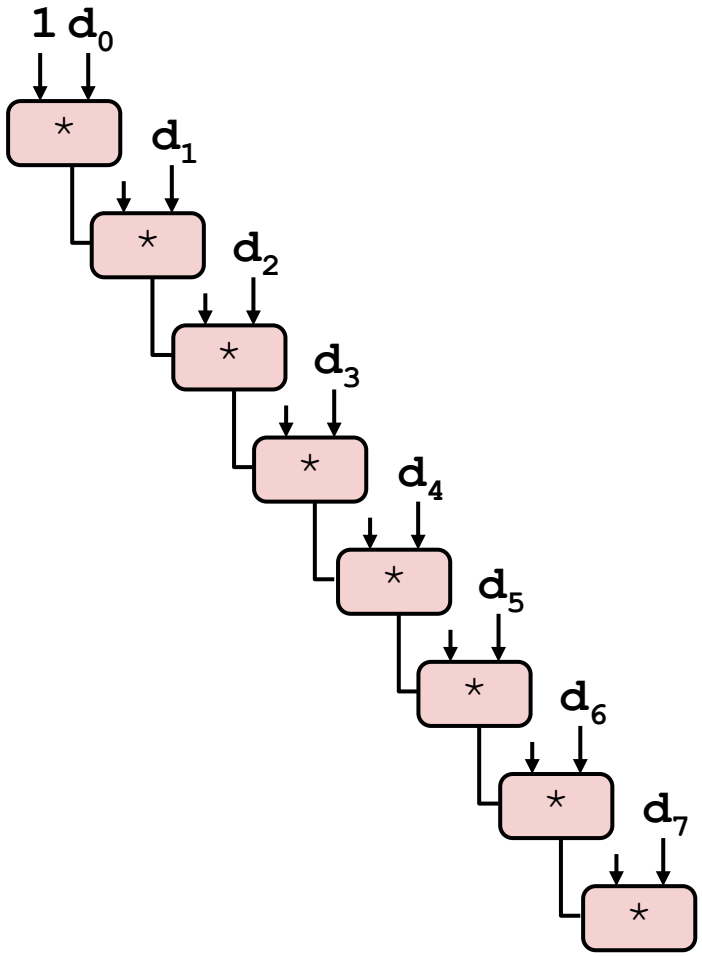
- Instruction level parallelism
- Latency versus throughput

	latency	*cycles/issue*
Integer Multiply	10	1

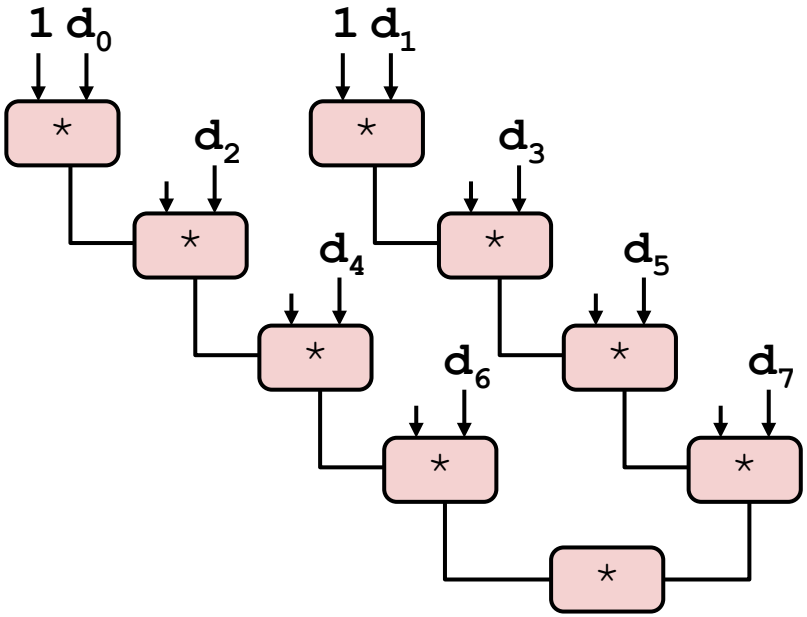


Last Time

- Consequence

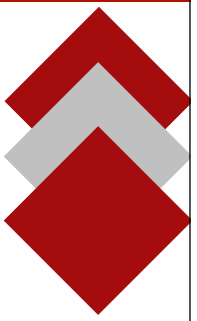


Twice as fast



Today

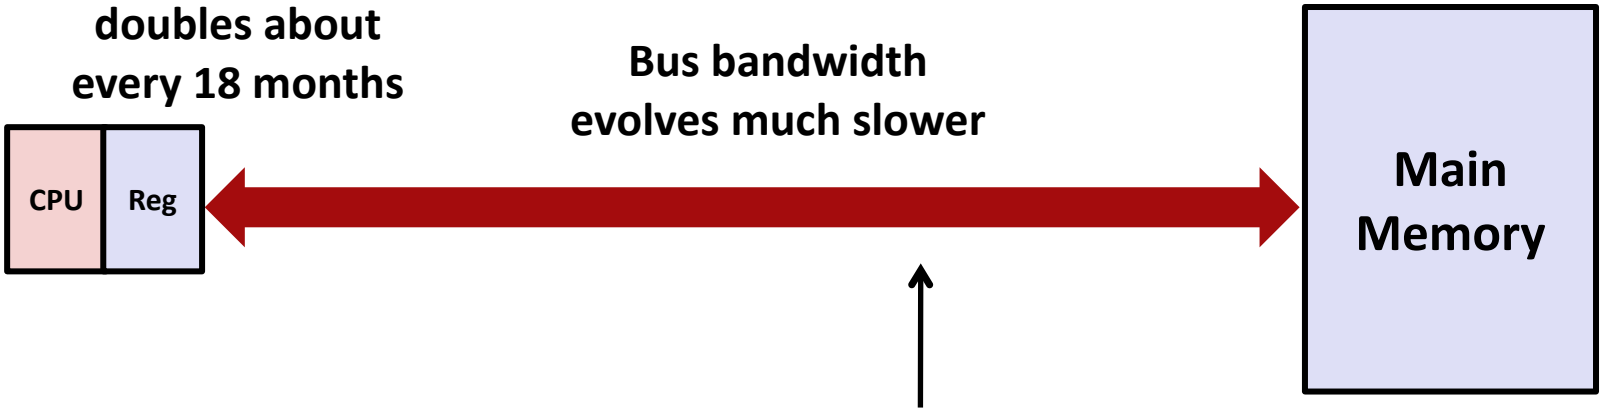
- **Memory hierarchy, caches, locality**
- **Cache organization**
- **Program optimization:**
  - Cache optimizations



Problem: Processor-Memory Bottleneck

Processor performance doubles about every 18 months

Bus bandwidth evolves much slower



Core 2 Duo:
Can process at least
256 Bytes/cycle
(1 SSE two operand add and mult)

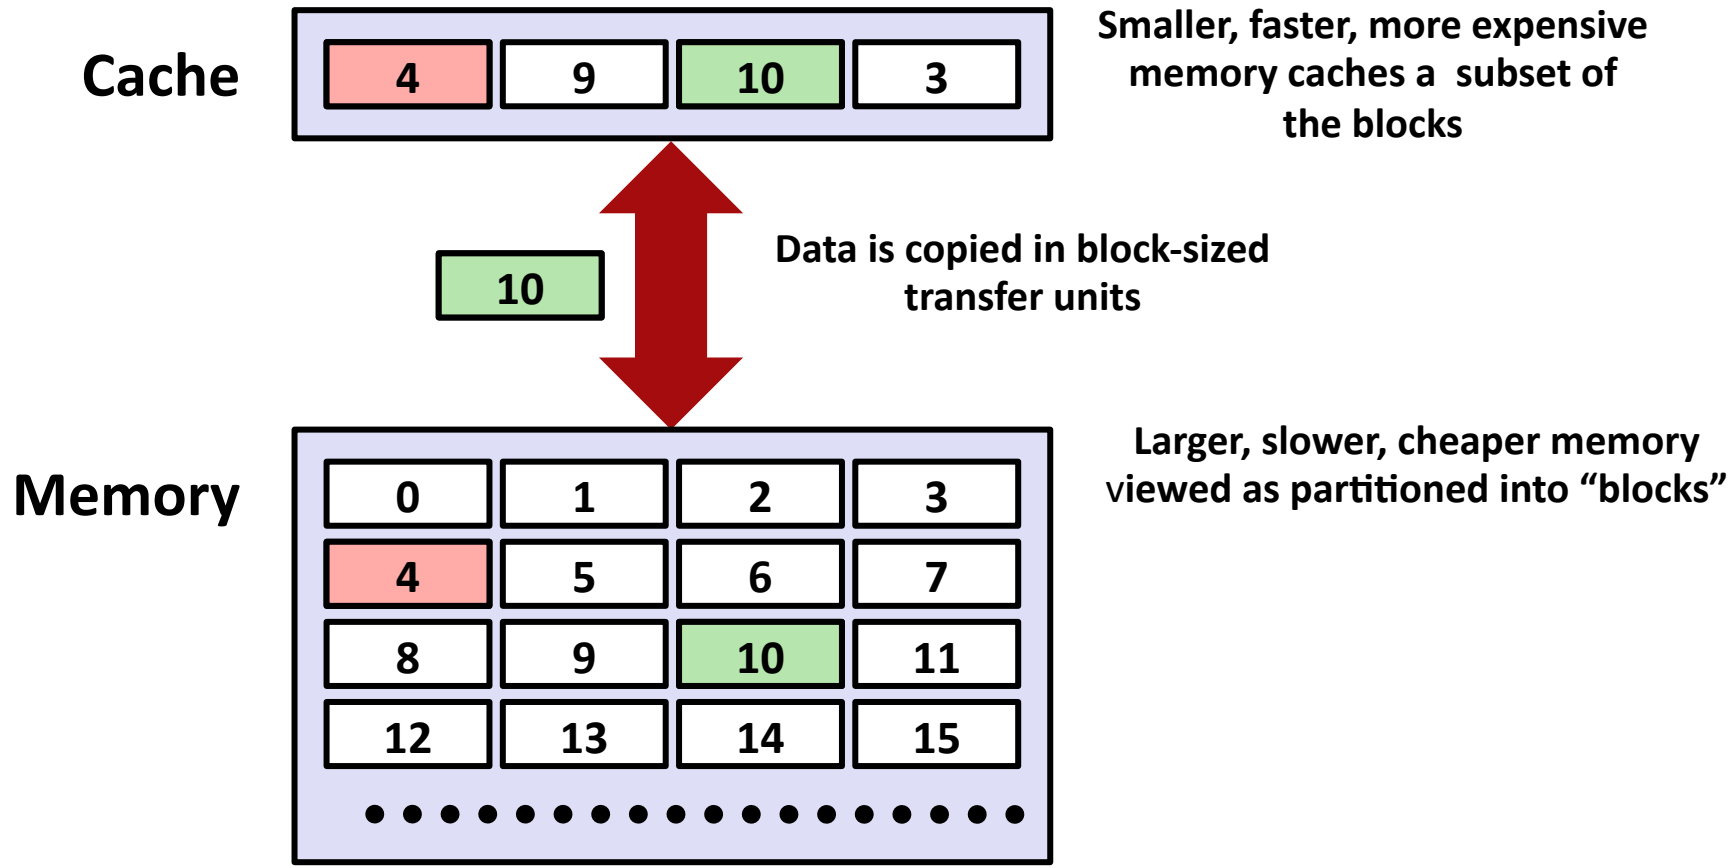
Core 2 Duo:
Bandwidth
2 Bytes/cycle
Latency
100 cycles

Solution: Caches

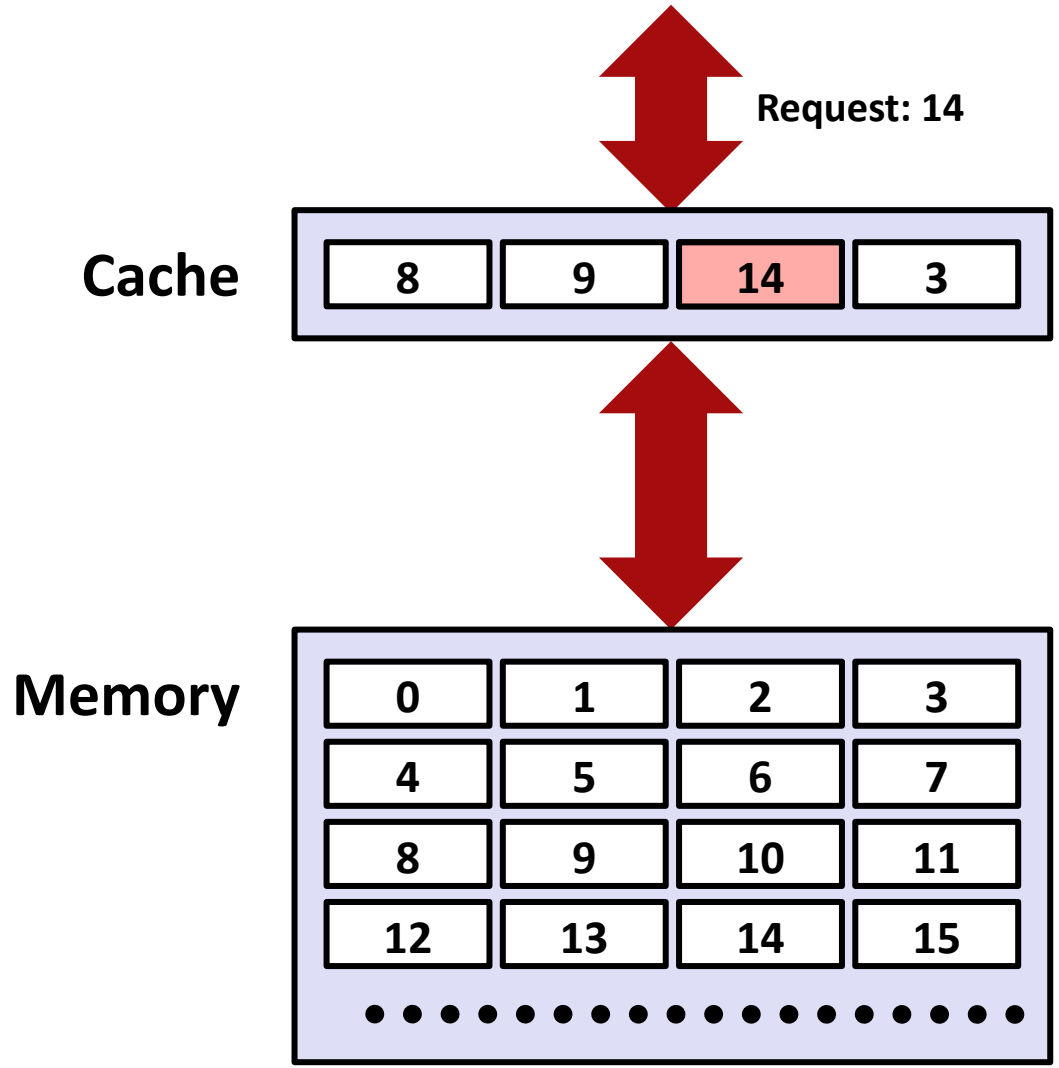
Cache

- **Definition: Computer memory with short access time used for the storage of frequently or recently used instructions or data**
  - From the French *cacher* 'to hide'
  - Memory contents *hidden* close to their point of use, in hopes of using them again in the future
  - As opposed to buffers/variables/etc, which are not hidden and require programmer management

General Cache Mechanics



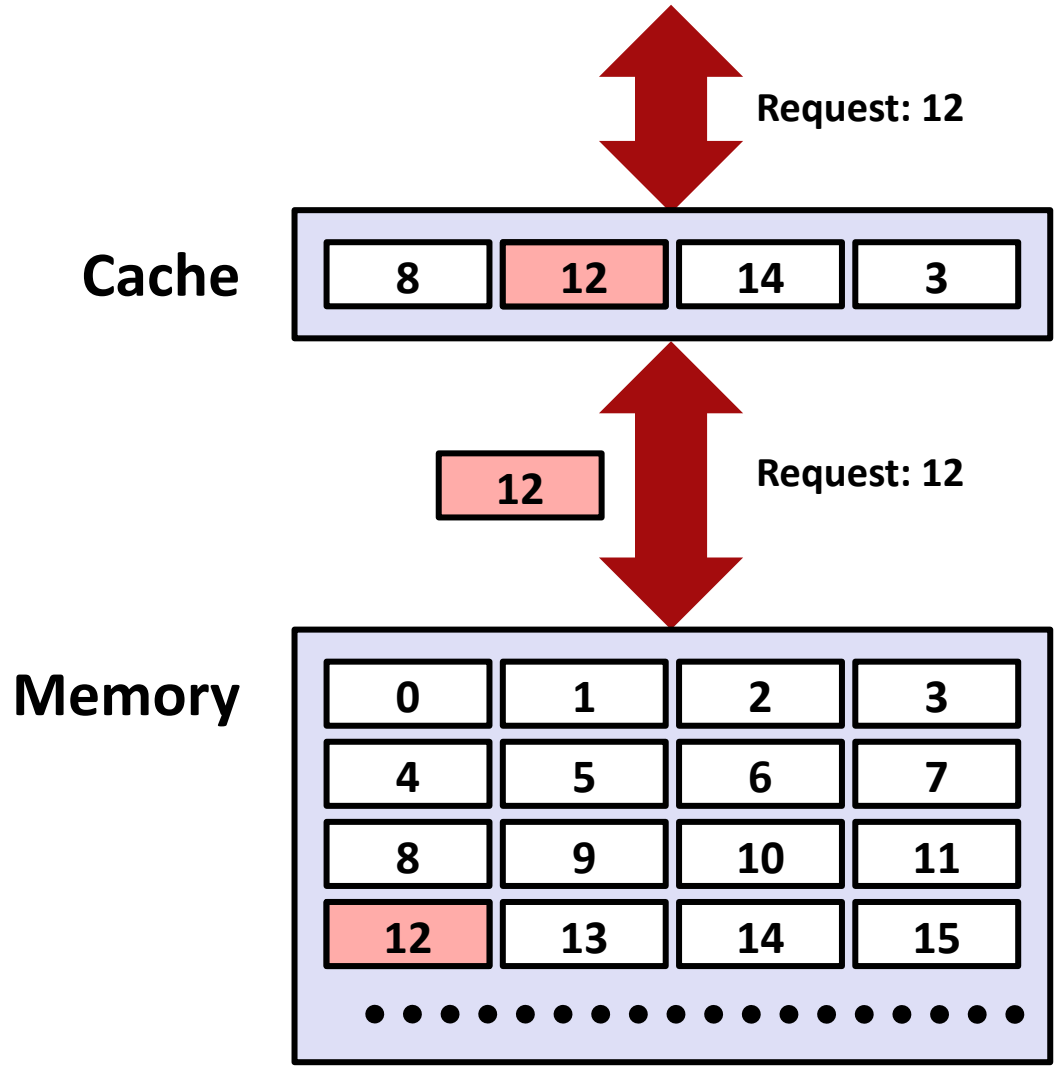
General Cache Concepts: Hit



Data in block b is needed

Block b is in cache:
Hit!

General Cache Concepts: Miss



Data in block b is needed

Block b is not in cache:
Miss!

Block b is fetched from memory

Block b is stored in cache

- **Placement policy:** determines where b goes
- **Replacement policy:** determines which block gets evicted (victim)

Cache Performance Metrics

- **Miss Rate**
  - Fraction of memory references not found in cache (misses / accesses) = 1 – hit rate
  - Typical numbers (in percentages):
    - 3-10% for L1
    - can be quite small (e.g., < 1%) for L2, depending on size, etc.
- **Hit Time**
  - Time to deliver a line in the cache to the processor
    - includes time to determine whether the line is in the cache
  - Typical numbers:
    - 1-2 clock cycle for L1
    - 5-20 clock cycles for L2
- **Miss Penalty**
  - Additional time required because of a miss
    - typically 50-200 cycles for main memory (Trend: increasing!)

Let us think about those numbers

- **Huge difference between a hit and a miss**
  - Could be 100x, if just L1 and main memory

- **Would you believe 99% hits is twice as good as 97%?**
  - Consider:
    cache hit time of 1 cycle
    miss penalty of 100 cycles

  - Average access time:

    97% hits: 1 cycle + 0.03 * 100 cycles = **4 cycles**

    99% hits: 1 cycle + 0.01 * 100 cycles = **2 cycles**

- **This is why "miss rate" is used instead of "hit rate"**

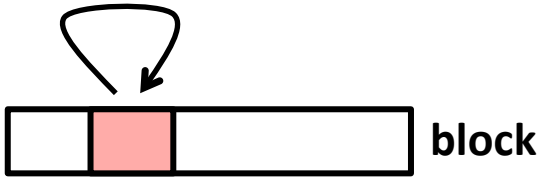
Types of Cache Misses

- **Cold (compulsory) miss**
  - Occurs on first access to a block
- **Capacity miss**
  - Occurs when the set of active cache blocks (working set) is larger than the cache size
  - Must evict a victim to make space for replacement block
- **Conflict miss**
  - Most hardware caches limit blocks to a small subset (sometimes a singleton) of the available cache slots
    - e.g., block *i* must be placed in slot (*i* mod 4)
  - Conflict misses occur when the cache is large enough, but multiple data objects all map to the same slot
    - e.g., referencing blocks 0, 8, 0, 8, ... would miss every time

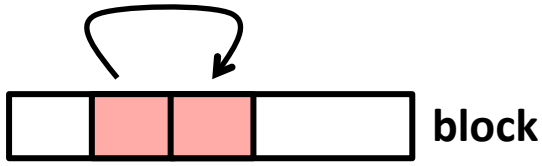
Why Caches Work

- **Locality: Programs tend to use data and instructions with addresses near or equal to those they have used recently**

- **Temporal locality:**
  - Recently referenced items are likely to be referenced again in the near future



- **Spatial locality:**
  - Items with nearby addresses tend to be referenced close together in time



- **Fundamental Law (almost): Programs with good locality run faster than programs with poor locality**

Example: Locality?

```
sum = 0;
for (i = 0; i < n; i++)
  sum += a[i];
return sum;
```

- **Data:**
  - Temporal: **`sum`** referenced in each iteration
  - Spatial: array **`a[]`** accessed in stride-1 pattern
- **Instructions:**
  - Temporal: cycle through loop repeatedly
  - Spatial: reference instructions in sequence

- **Being able to assess the locality of code is a crucial skill for a programmer**

Locality Example #1

```
int sum_array_rows(int a[M][N])
{
    int i, j, sum = 0;

    for (i = 0; i < M; i++)
        for (j = 0; j < N; j++)
            sum += a[i][j];
    return sum;
}
```

Locality Example #2

```
int sum_array_cols(int a[M][N])
{
    int i, j, sum = 0;

    for (j = 0; j < N; j++)
        for (i = 0; i < M; i++)
            sum += a[i][j];
    return sum;
}
```

Locality Example #3

```
int sum_array_3d(int a[M][N][N])
{
    int i, j, k, sum = 0;

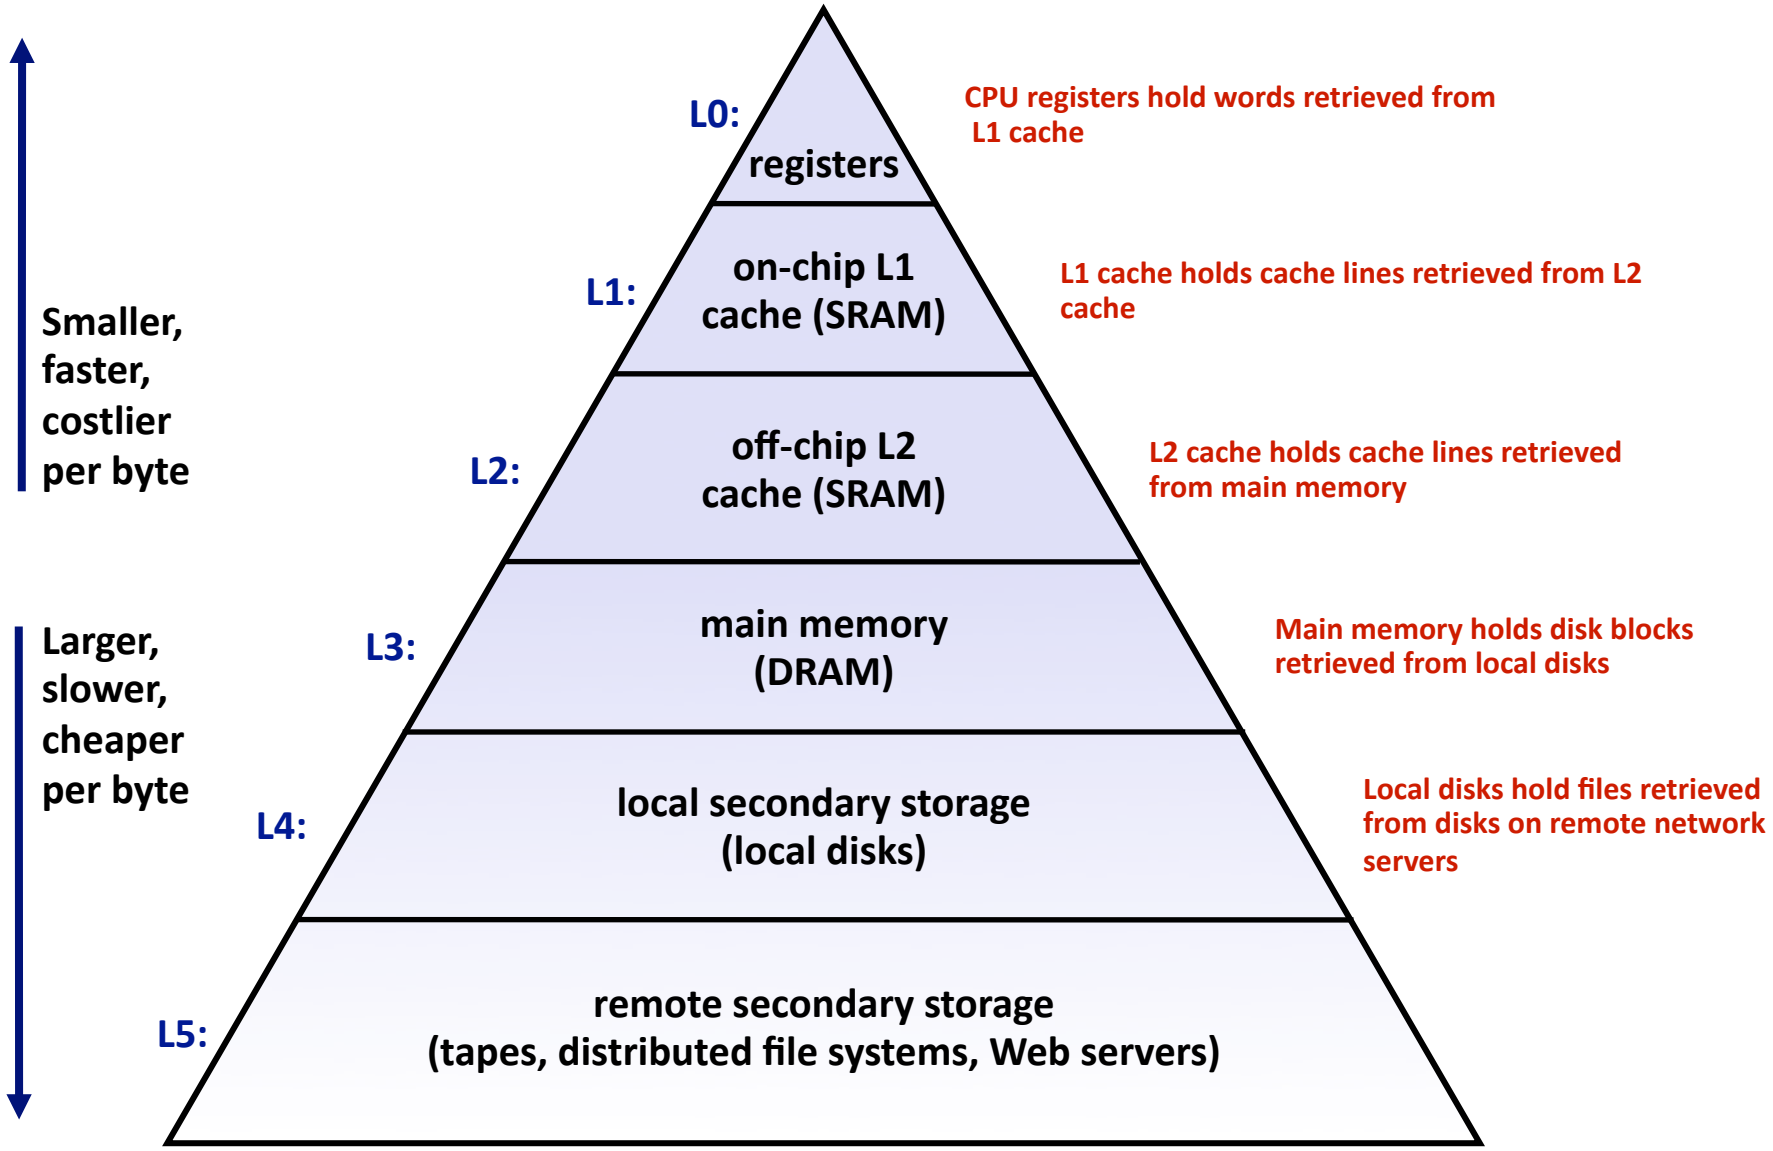
    for (i = 0; i < M; i++)
        for (j = 0; j < N; j++)
            for (k = 0; k < N; k++)
                sum += a[k][i][j];
    return sum;
}
```

- How can it be fixed?

Memory Hierarchies

- **Fundamental and enduring properties of hardware:**
  - Faster storage technologies almost always cost more per byte and have lower capacity
  - The gaps between memory technology speeds are widening
    - True of registers ↔ DRAM, DRAM ↔ disk, etc.
- **Fundamental and enduring property of software:**
  - Well-written programs tend to exhibit good locality
- **These properties complement each other beautifully**
- **They suggest an approach for organizing memory and storage systems known as a memory hierarchy**

An Example Memory Hierarchy



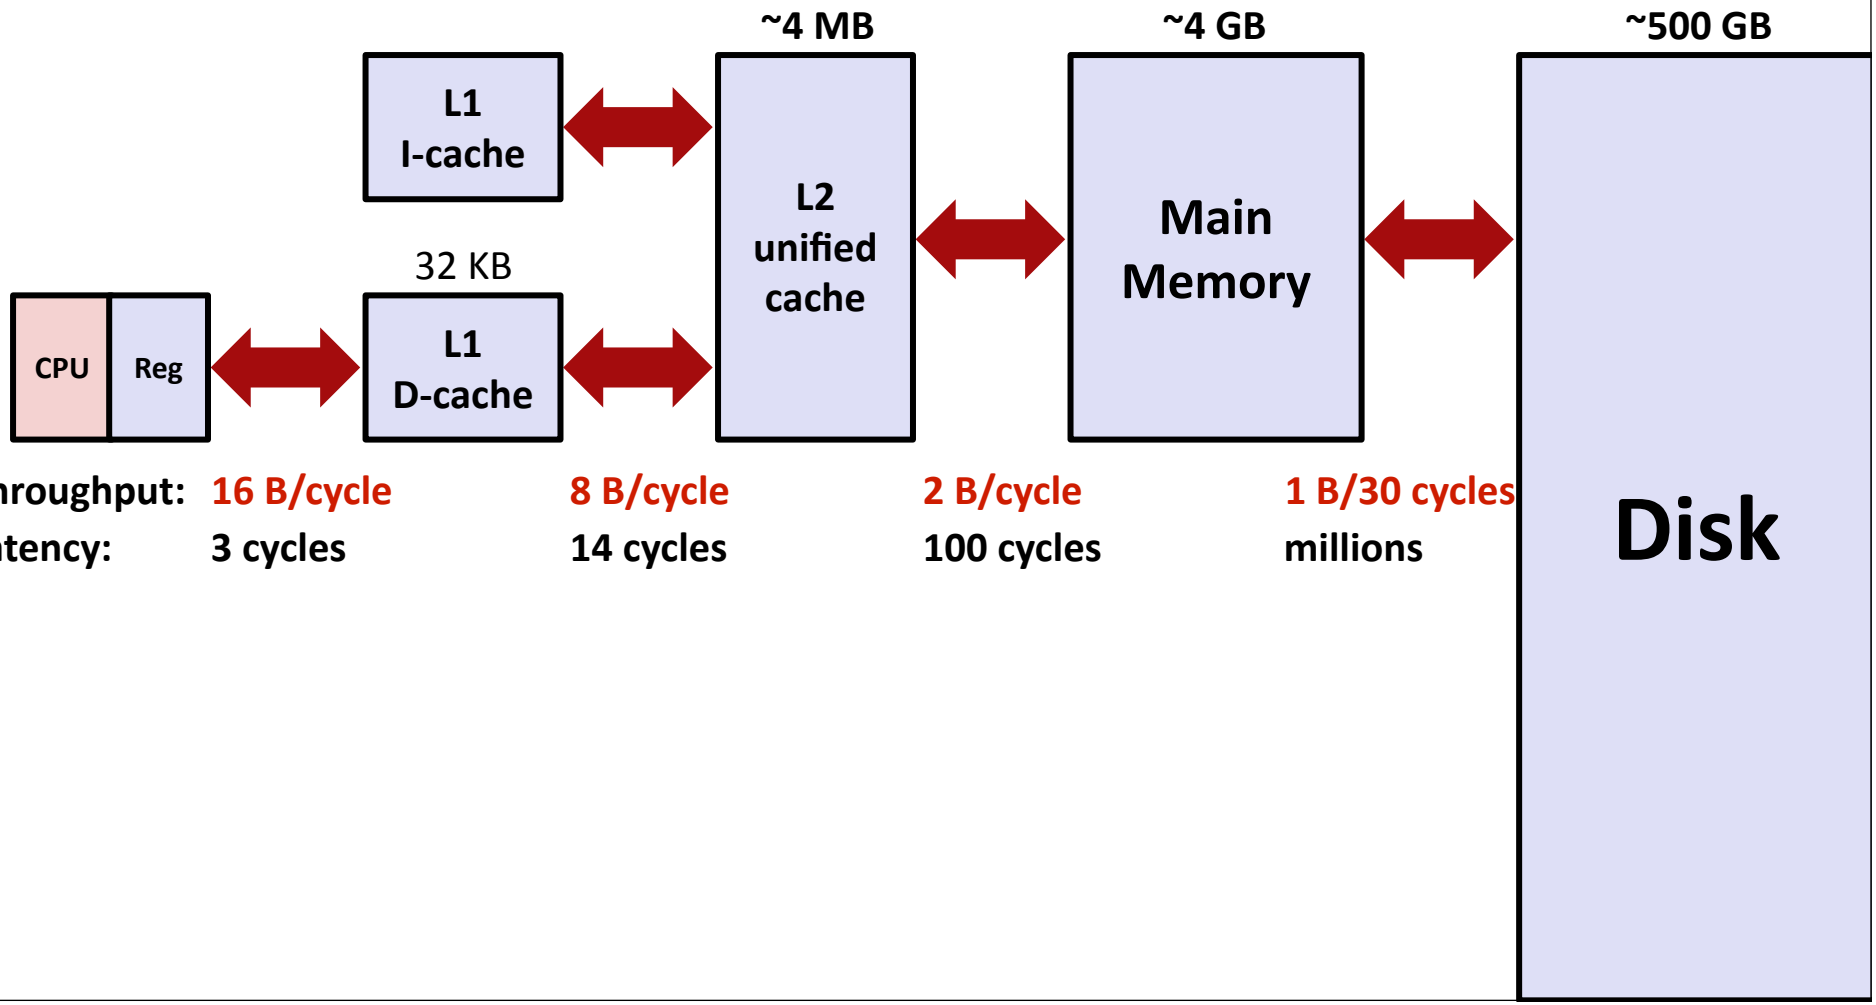
Examples of Caching in the Hierarchy

Cache Type	What is Cached?	Where is it Cached?	Latency (cycles)	Managed By
Registers	4-byte words	CPU core	0	Compiler
TLB	Address translations	On-Chip TLB	0	Hardware
L1 cache	64-bytes block	On-Chip L1	1	Hardware
L2 cache	64-bytes block	Off-Chip L2	10	Hardware
Virtual Memory	4-KB page	Main memory	100	Hardware+OS
Buffer cache	Parts of files	Main memory	100	OS
Network buffer cache	Parts of files	Local disk	10,000,000	AFS/NFS client
Browser cache	Web pages	Local disk	10,000,000	Web browser
Web cache	Web pages	Remote server disks	1,000,000,000	Web proxy server

Memory Hierarchy: Core 2 Duo

Not drawn to scale

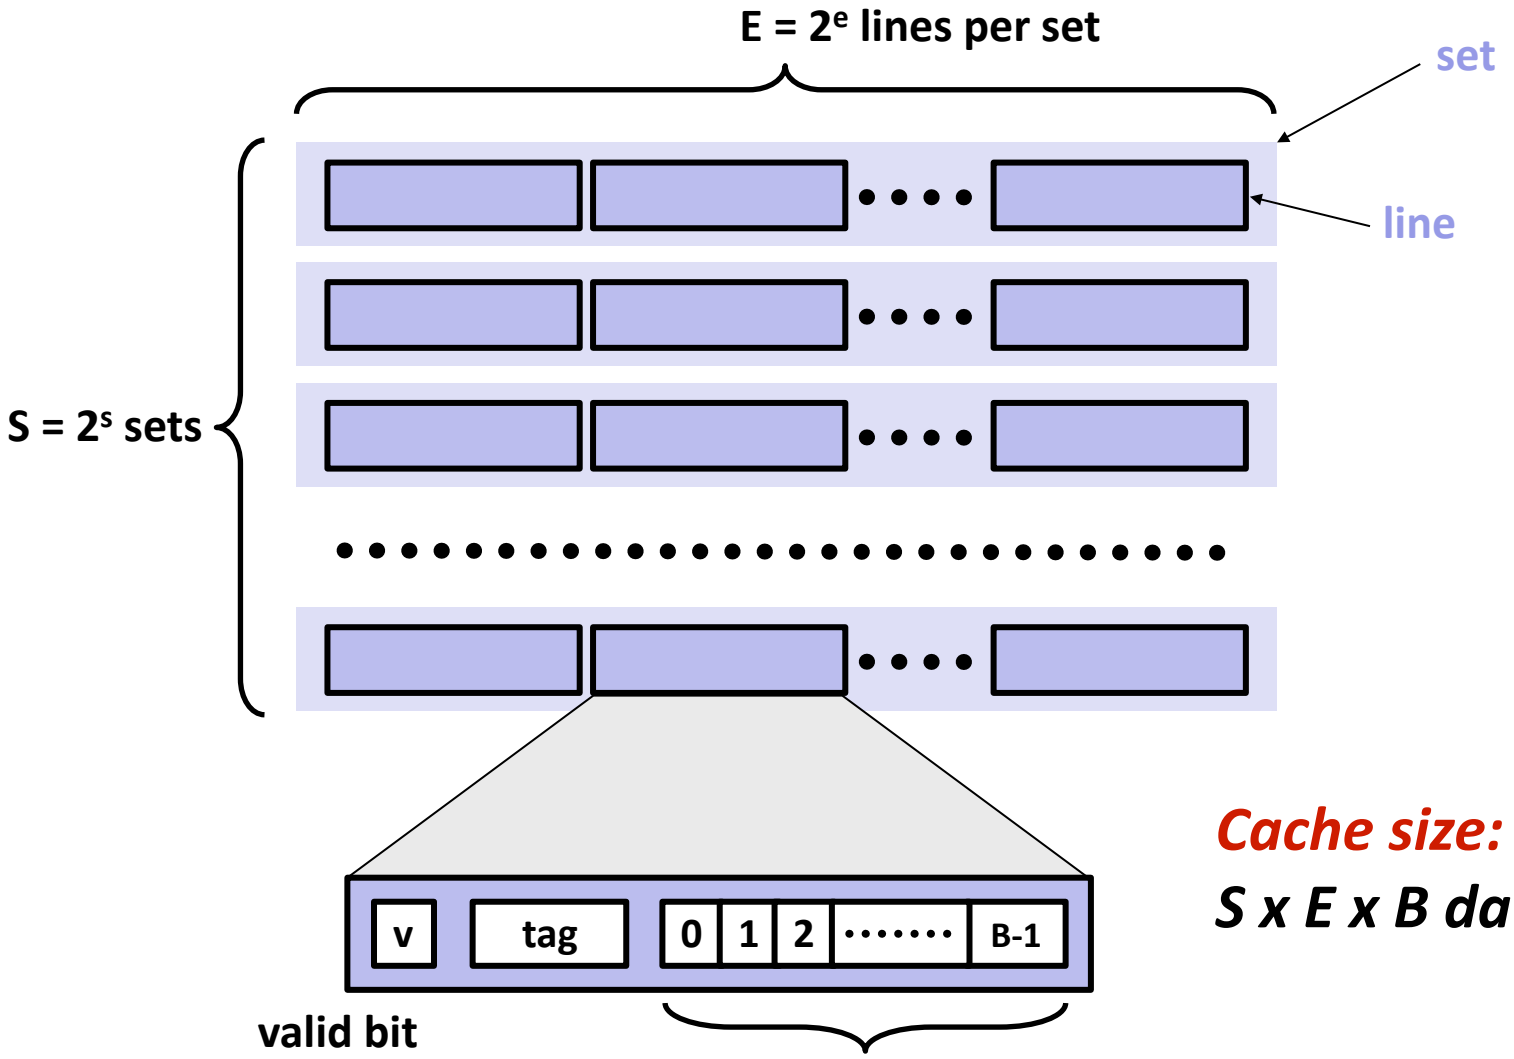
L1/L2 cache: 64 B blocks



Today

- Memory hierarchy, caches, locality
- **Cache organization**
- Program optimization:
  - Cache optimizations

General Cache Organization (S, E, B)

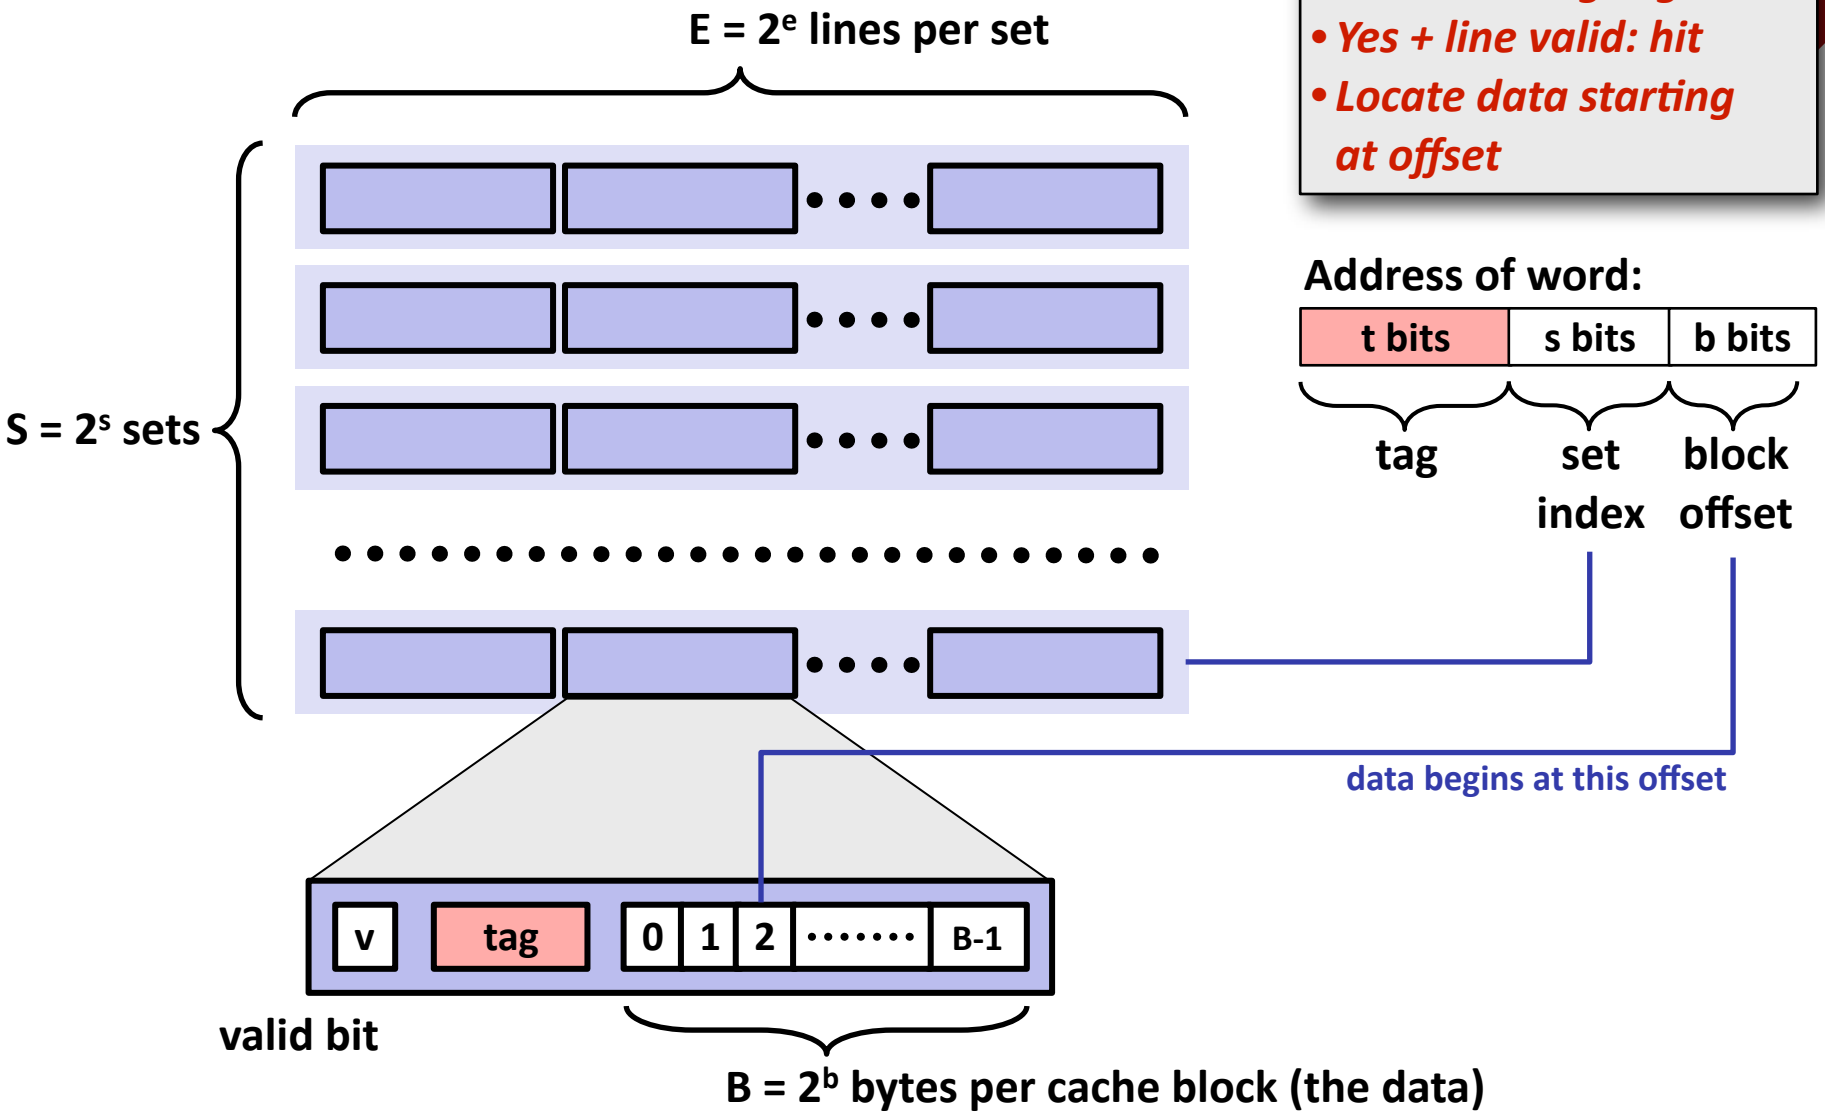


Cache size:

S x E x B data bytes

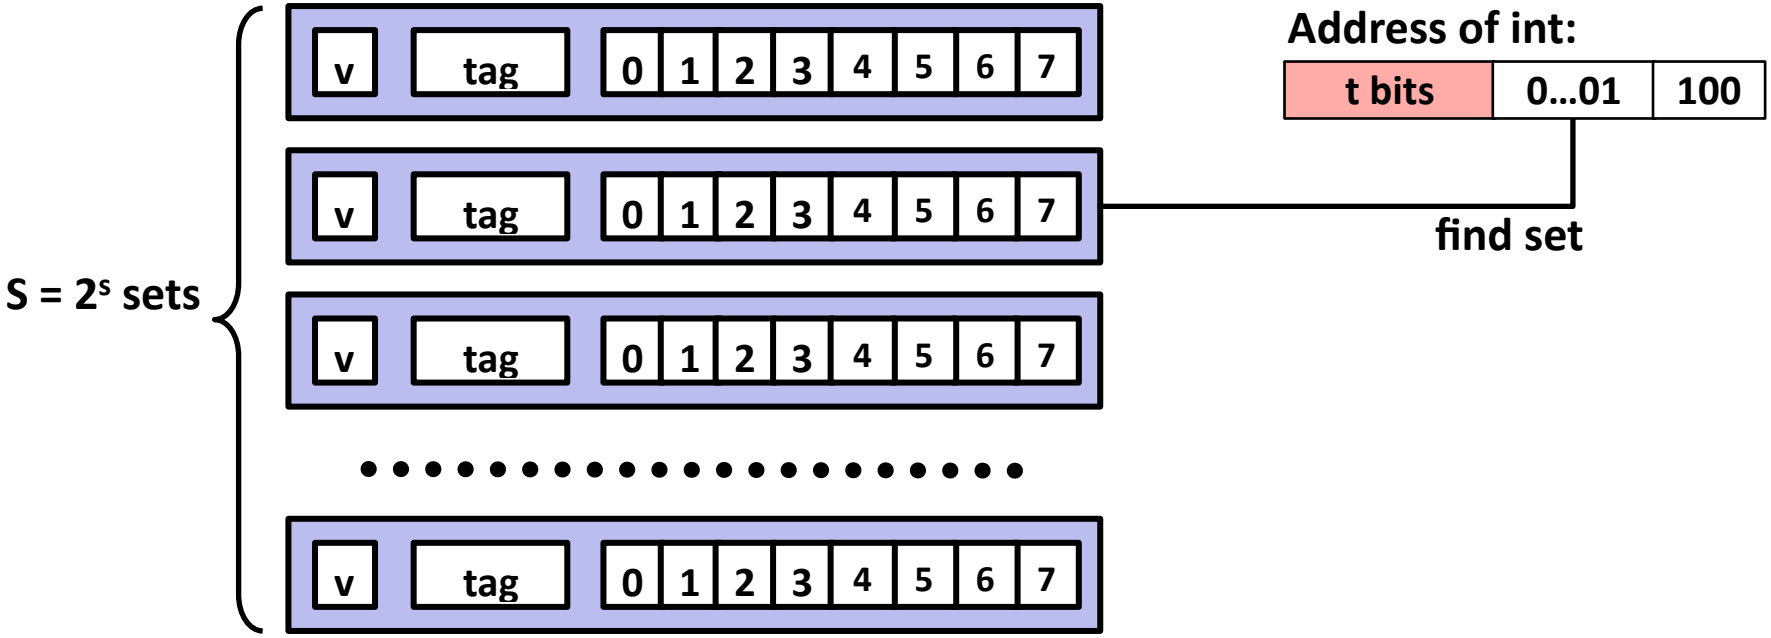
Cache Read

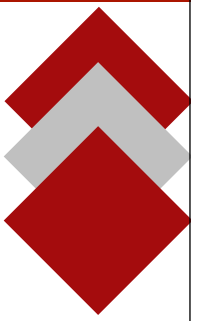
- *Locate set*
- *Check if any line in set has matching tag*
- *Yes + line valid: hit*
- *Locate data starting at offset*



Example: Direct Mapped Cache (E = 1)

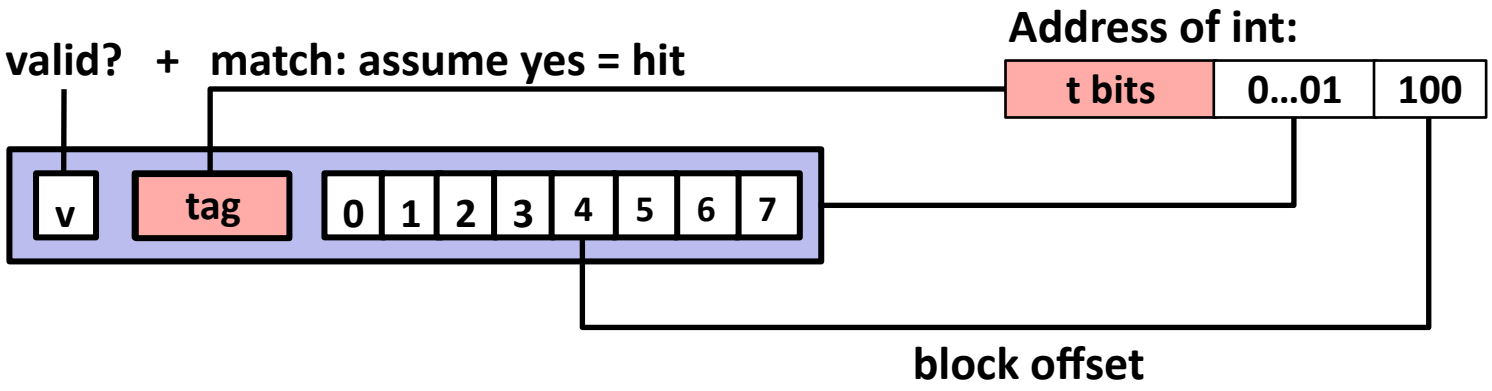
Direct mapped: One line per set
Assume: cache block size 8 bytes





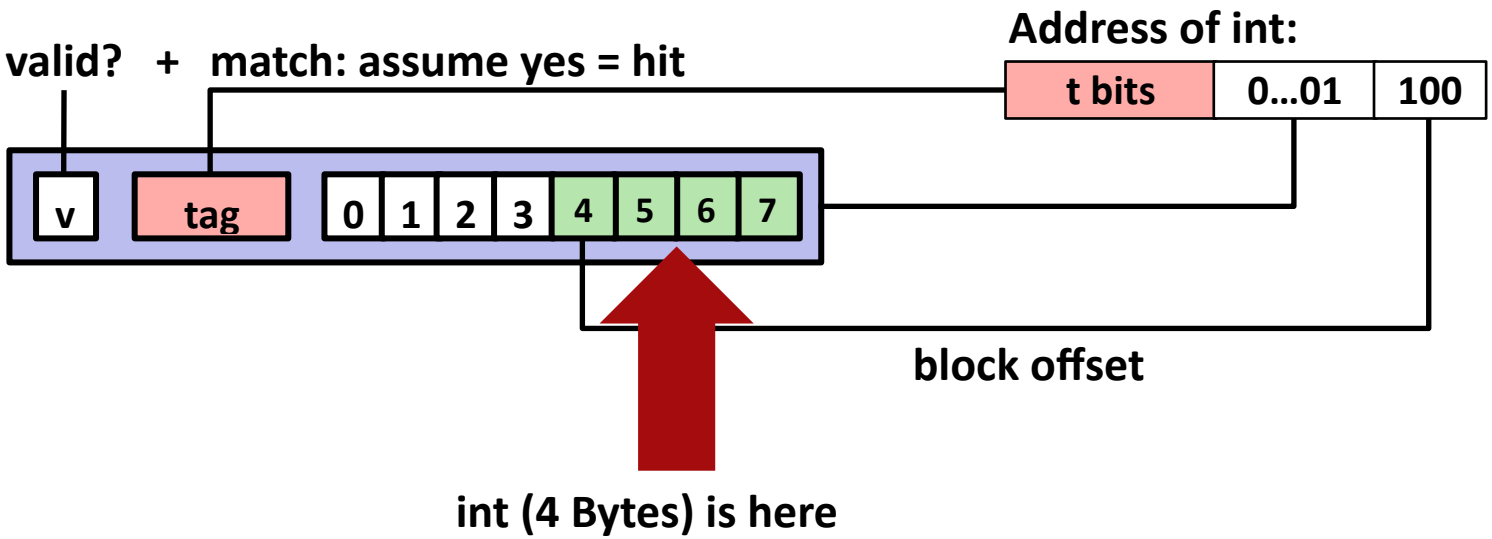
Example: Direct Mapped Cache (E = 1)

Direct mapped: One line per set
Assume: cache block size 8 bytes



Example: Direct Mapped Cache (E = 1)

Direct mapped: One line per set
Assume: cache block size 8 bytes



No match: old line is evicted and replaced

Example

Ignore the variables sum, i, j

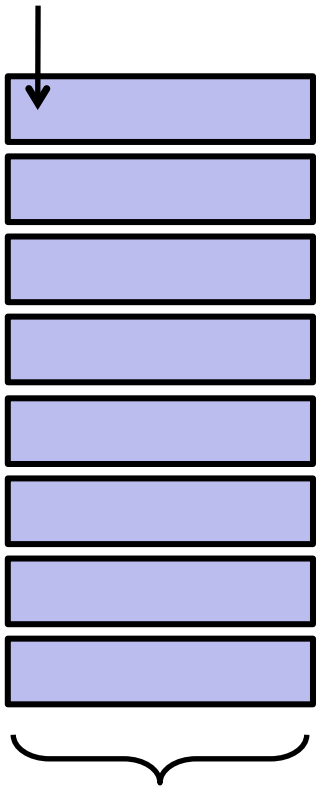
```
int sum_array_rows(double a[16][16])
{
    int i, j;
    double sum = 0;

    for (i = 0; i < 16; i++)
        for (j = 0; j < 16; j++)
            sum += a[i][j];
    return sum;
}
```

```
int sum_array_cols(double a[16][16])
{
    int i, j;
    double sum = 0;

    for (j = 0; i < 16; i++)
        for (i = 0; j < 16; j++)
            sum += a[i][j];
    return sum;
}
```

assume: cold (empty) cache, a[0][0] goes here

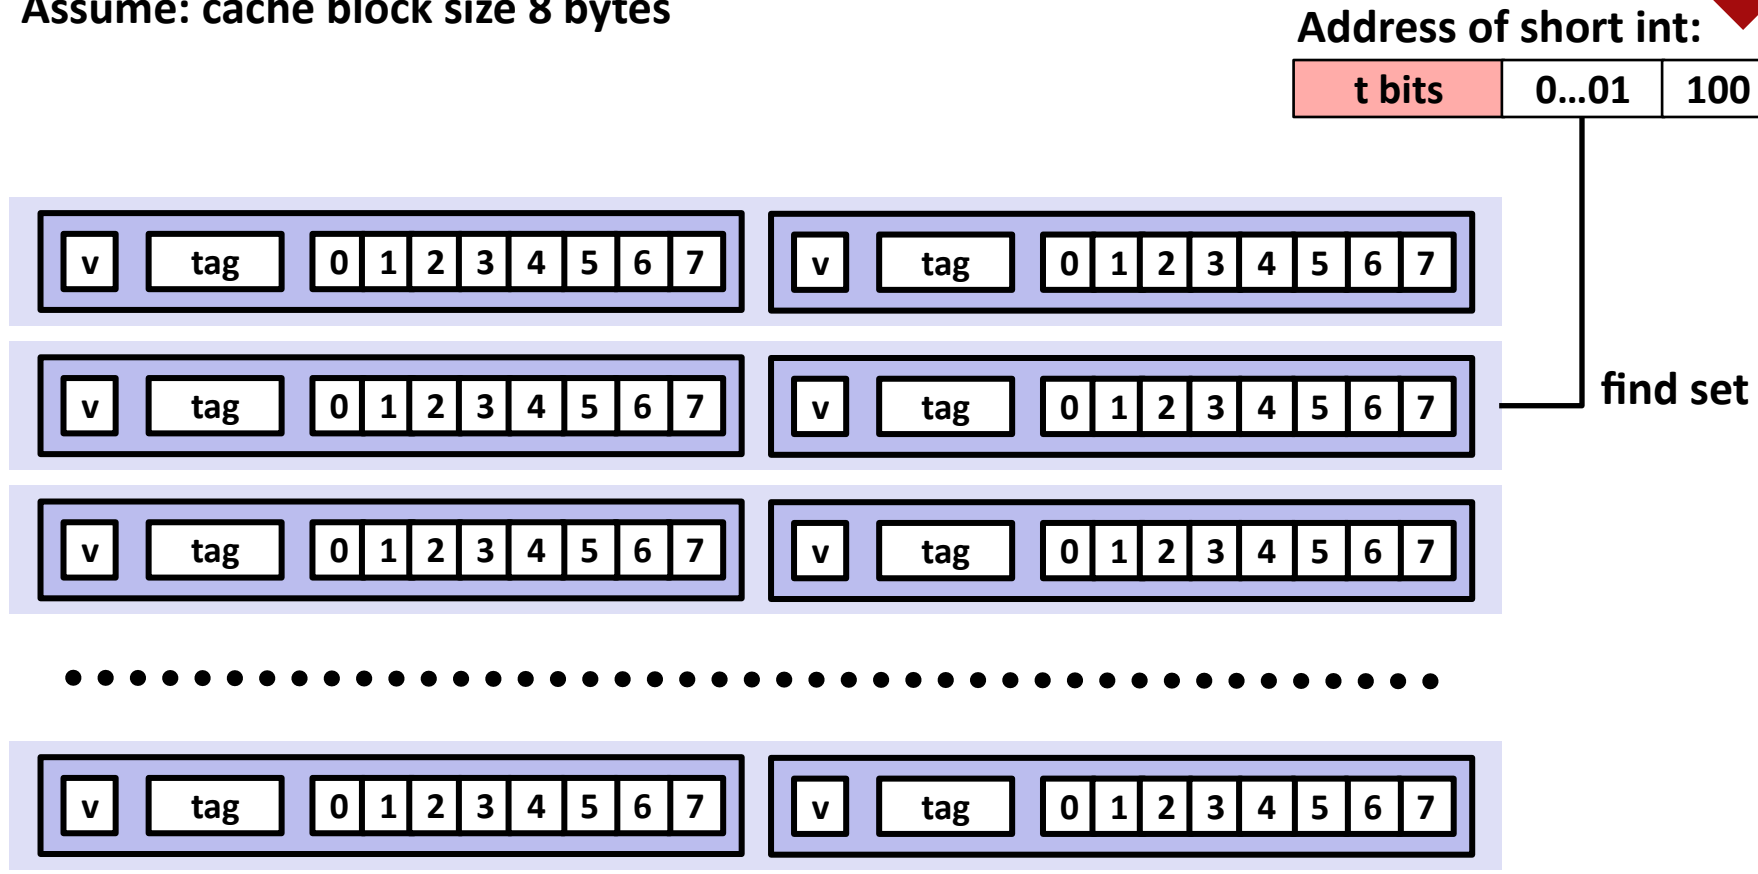


32 B = 4 doubles

E-way Set Associative Cache (Here: E = 2)

E = 2: Two lines per set

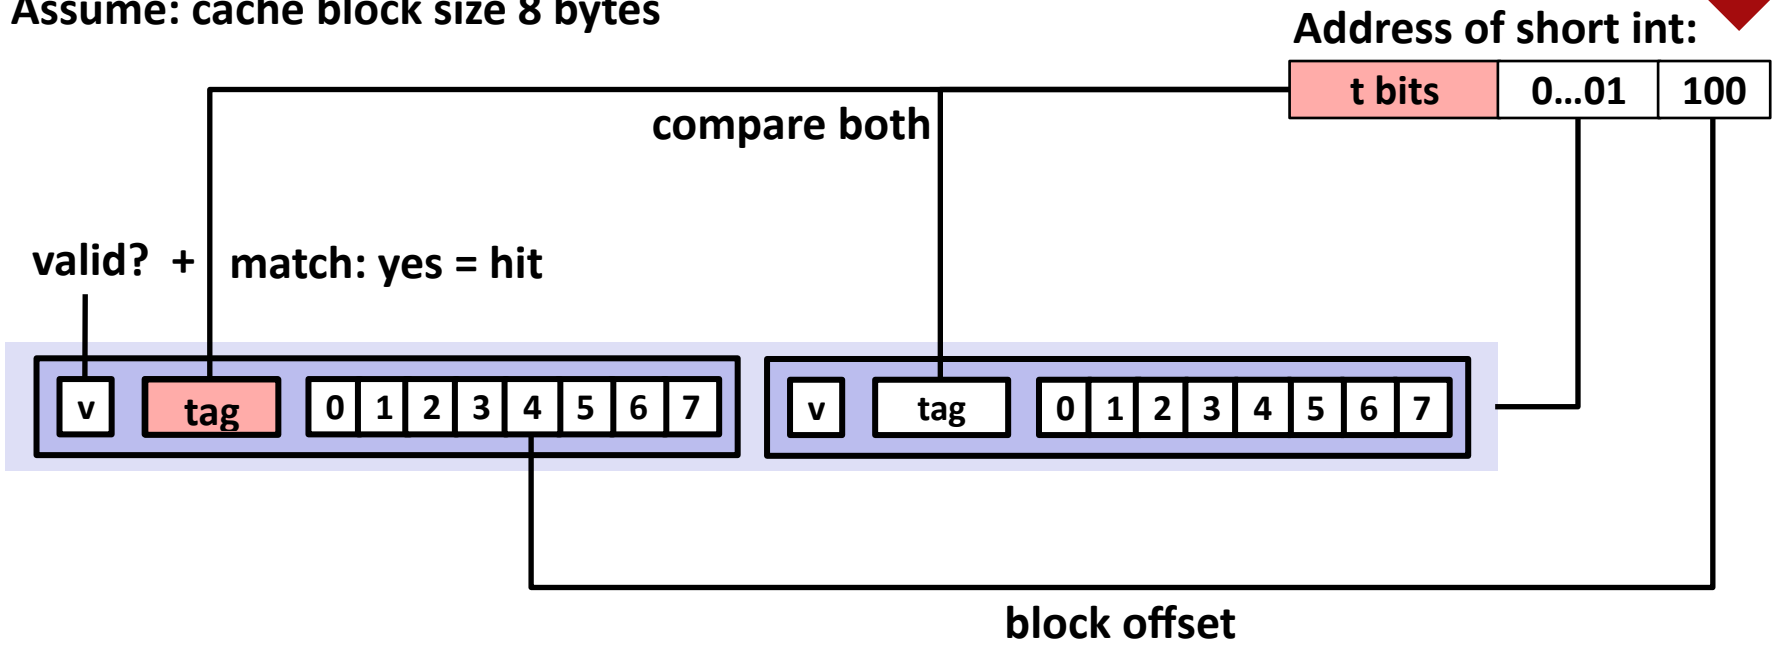
Assume: cache block size 8 bytes



E-way Set Associative Cache (Here: E = 2)

E = 2: Two lines per set

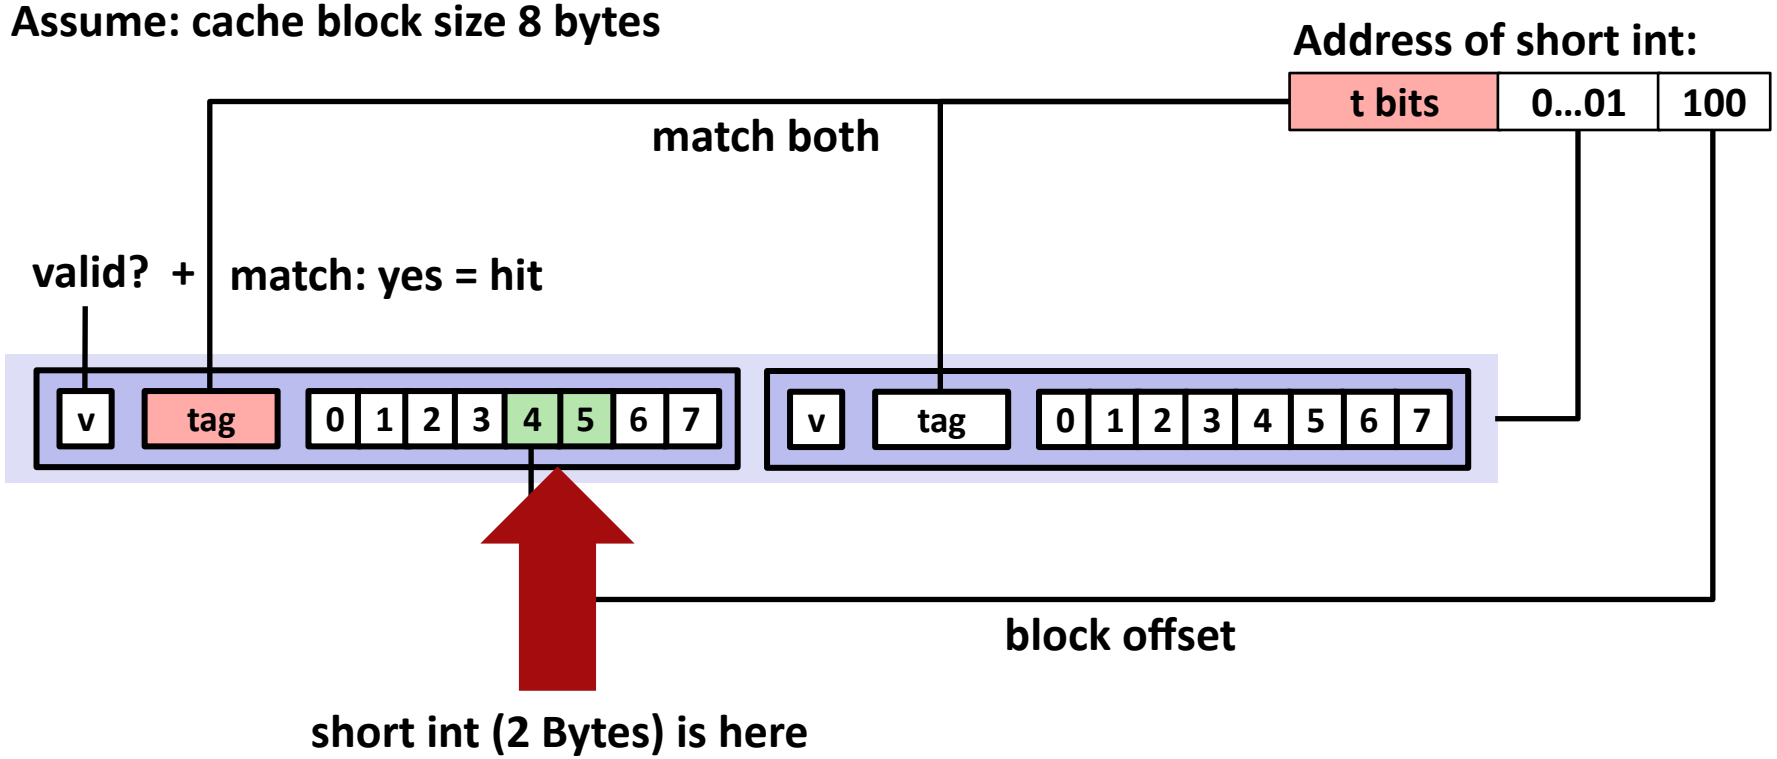
Assume: cache block size 8 bytes



E-way Set Associative Cache (Here: E = 2)

E = 2: Two lines per set

Assume: cache block size 8 bytes



No match:

- One line in set is selected for eviction and replacement
- Replacement policies: random, least recently used (LRU), …

Example

```
int sum_array_rows(double a[16][16])
{
    int i, j;
    double sum = 0;

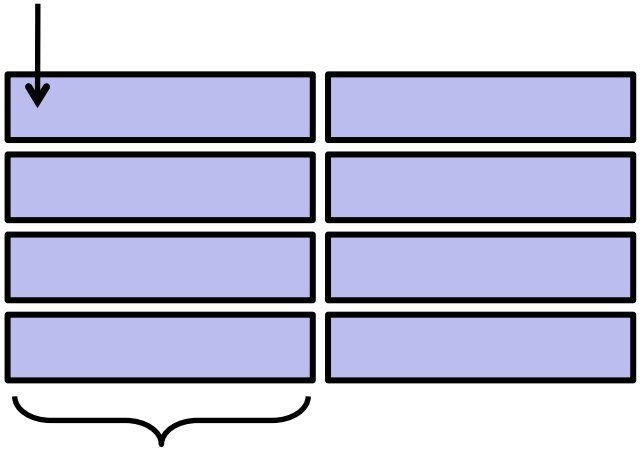
    for (i = 0; i < 16; i++)
        for (j = 0; j < 16; j++)
            sum += a[i][j];
    return sum;
}
```

```
int sum_array_rows(double a[16][16])
{
    int i, j;
    double sum = 0;

    for (j = 0; i < 16; i++)
        for (i = 0; j < 16; j++)
            sum += a[i][j];
    return sum;
}
```

Ignore the variables sum, i, j

assume: cold (empty) cache,
a[0][0] goes here



32 B = 4 doubles

What about writes?

- **Multiple copies of data exist:**
  - L1, L2, Main Memory, Disk
- **What to do when a write-hit occurs?**
  - Write-through (write immediately to memory)
  - Write-back (defer write to memory until replacement of line)
    - Need a dirty bit (line different from memory or not)
- **What to do when a write-miss occurs?**
  - Write-allocate (load into cache, update line in cache)
    - Good if more writes to the location follow
  - No-write-allocate (writes immediately to memory)
- **Typical**
  - Write-through + No-write-allocate
  - **Write-back + Write-allocate**

Software Caches are More Flexible

- **Examples**
  - File system buffer caches, web browser caches, etc.

- **Some design differences**
  - Almost always fully associative
    - so, no placement restrictions
    - index structures like hash tables are common
  - Often use complex replacement policies
    - misses are very expensive when disk or network involved
    - worth thousands of cycles to avoid them
  - Not necessarily constrained to single “block” transfers
    - may fetch or write-back in larger units, opportunistically

Today

- Memory hierarchy, caches, locality
- Cache organization
- **Program optimization:**
  - Cache optimizations

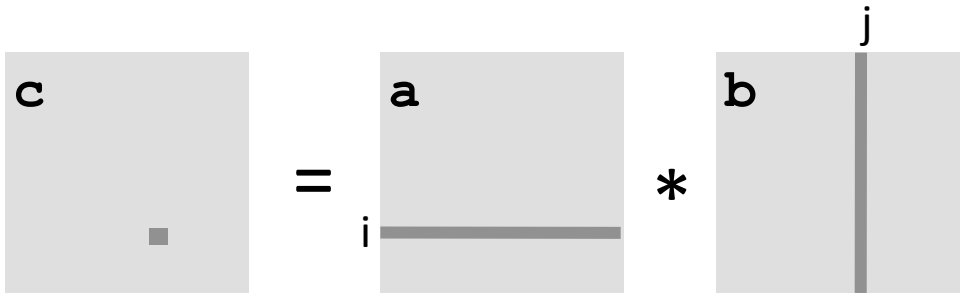
Optimizations for the Memory Hierarchy

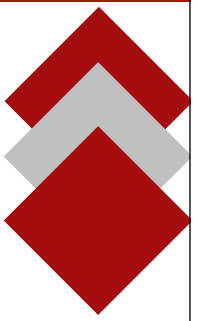
- **Write code that has locality**
  - Spatial: access data contiguously
  - Temporal: make sure access to the same data is not too far apart in time
- **How to achieve?**
  - Proper choice of algorithm
  - Loop transformations
- **Cache versus register level optimization:**
  - In both cases locality desirable
  - Register space much smaller + requires scalar replacement to exploit temporal locality
  - Register level optimizations include exhibiting instruction level parallelism (conflicts with locality)

Example: Matrix Multiplication

```
c = (double *) calloc(sizeof(double), n*n);

/* Multiply n x n matrices a and b  */
void mmm(double *a, double *b, double *c, int n) {
    int i, j, k;
    for (i = 0; i < n; i++)
        for (j = 0; j < n; j++)
            for (k = 0; k < n; k++)
            c[i*n+j] += a[i*n + k]*b[k*n + j];
}
```





Cache Miss Analysis

- **Assume:**
  - Matrix elements are doubles
  - Cache block = 8 doubles
  - Cache size C << n (much smaller than n)

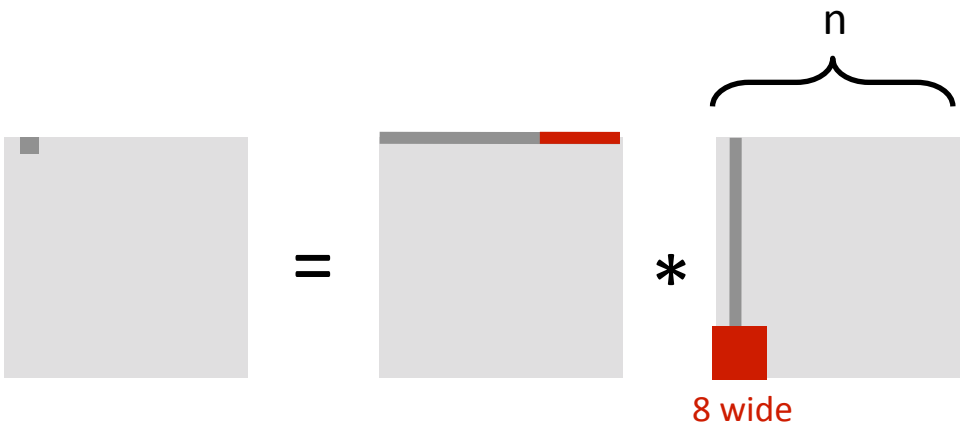
- **First iteration:**
  - n/8 + n = 9n/8 misses

  - Afterwards in cache: (schematic)

Cache Miss Analysis

- **Assume:**
  - Matrix elements are doubles
  - Cache block = 8 doubles
  - Cache size C << n (much smaller than n)

- **Second iteration:**
  - Again:
    n/8 + n = 9n/8 misses

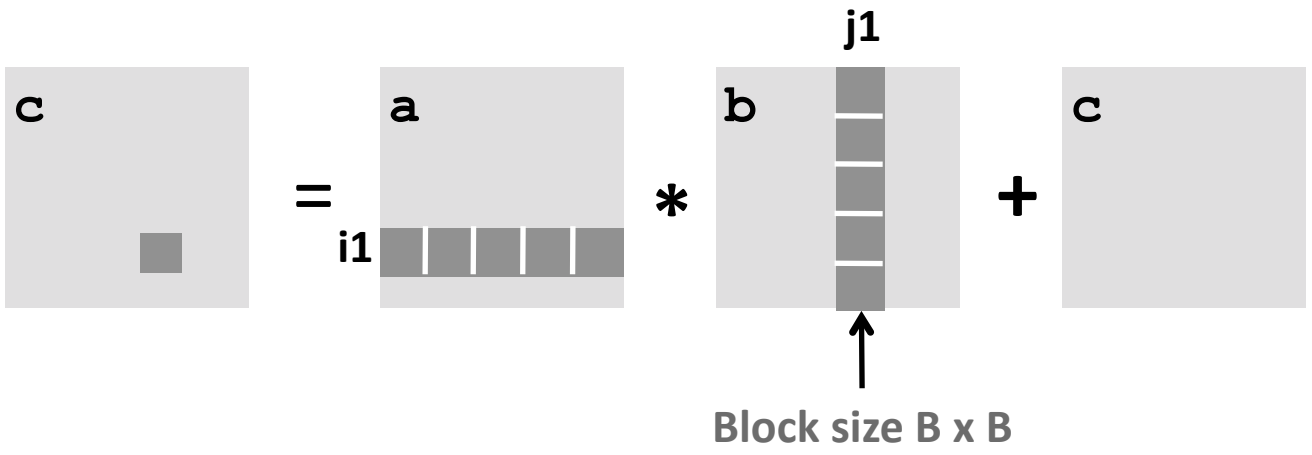


- **Total misses:**
  - $9n/8 * n^2 = (9/8) * n^3$

Blocked Matrix Multiplication

```
c = (double *) calloc(sizeof(double), n*n);

/* Multiply n x n matrices a and b  */
void mmm(double *a, double *b, double *c, int n) {
    int i, j, k;
    for (i = 0; i < n; i+=B)
        for (j = 0; j < n; j+=B)
            for (k = 0; k < n; k+=B)
                /* B x B mini matrix multiplications */
                for (i1 = i; i1 < i+B; i++)
                    for (j1 = j; j1 < j+B; j++)
                        for (k1 = k; k1 < k+B; k++)
                            c[i1*n+j1] += a[i1*n + k1]*b[k1*n + j1];
}
```



Cache Miss Analysis

- **Assume:**
  - Cache block = 8 doubles
  - Cache size C << n (much smaller than n)
  - Three blocks ■ fit into cache: $3B^2 < C$

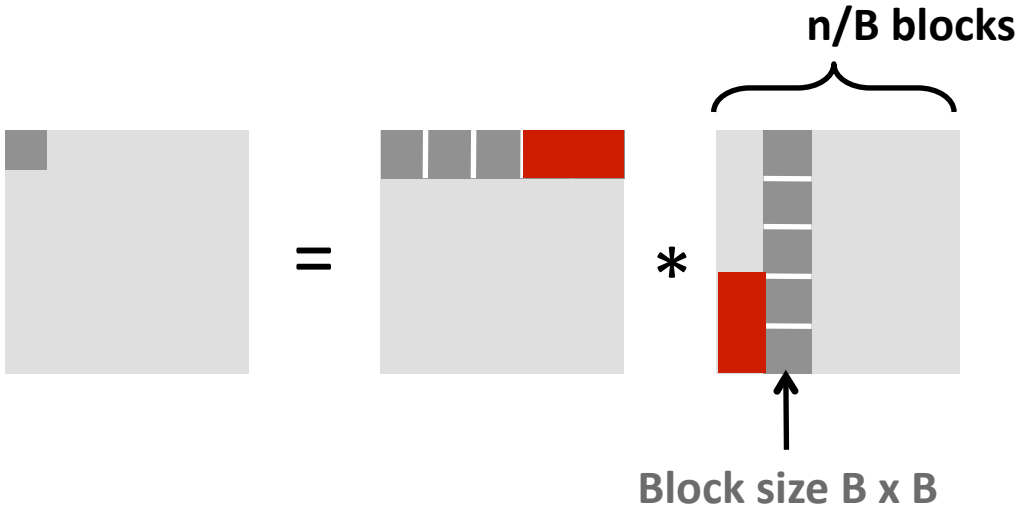
- **First (block) iteration:**
  - $B^2/8$ misses for each block
  - $2n/B * B^2/8 = nB/4$ (omitting matrix c)

  - Afterwards in cache (schematic)

Cache Miss Analysis

- **Assume:**
  - Cache block = 8 doubles
  - Cache size C << n (much smaller than n)
  - Three blocks ■ fit into cache: 3B2 < C

- **Second (block) iteration:**
  - Same as first iteration
  - $2n/B * B^2/8 = nB/4$



- **Total misses:**
  - $nB/4 * (n/B)^2 = n^3/(4B)$

Matrix Multiplication: The Bottom Line

- **No blocking: (9/8) * n^3**
- **Blocking: 1/(4B) * n^3**

- **Suggest largest possible block size B, but limit $3B^2 < C$! (can possibly be relaxed a bit, but there is a limit for B)**

- **Reason for dramatic difference:**
  - Matrix multiplication has inherent temporal locality:
    - Input data: $3n^2$, computation $2n^3$
    - Every array elements used O(n) times!
  - But program has to be written properly

Summary

- **Memory hierarchy, caches, locality**
- **Cache organization**
- **Program optimization:**
  - Cache optimizations

- **Next Time: Exceptions**
  - Traps, Faults, Aborts, Interrupts
  - Processes
  - Context Switch
  - **`fork, exit`**
